

IDAHO NATIONAL ENGINEERING  
ENVIRONMENTAL LABORATORY PUBLIC MEETING

Proposed Cleanup Plans for Naval Reactors Facility  
and Argonne National Laboratory-West

**FINAL**

January 22, 1998  
Idaho Falls, Idaho  
6:30 p.m.

***ORIGINAL***

Nancy Schwartz Reporting

IDAHO FALLS, IDAHO, THURSDAY, JANUARY 22, 1998

MR. SIMPSON: Welcome to tonight's meeting. I also want to welcome those who are receiving extra credit for being here. I'm Erik Simpson. I'm the INEEL Community Relations Plan Coordinator for the Environmental Restoration Program.

We're here tonight to discuss the results of two Comprehensive Remedial Investigation/Feasibility Studies. These are environmental investigations. The first involves Argonne National -- first involves the Naval Reactors Facility, which is managed by the DOE Naval Reactors Branch. The second project that we're going to be discussing tonight involves Argonne National Laboratory-West, which is managed by DOE-Chicago because of its ties to the University of Chicago.

As you'll see from both of these presentations, these facilities have had a lengthy past in developing nuclear reactors and research and technology. And we're here tonight to discuss the resulting contamination problems and the steps that the Department of Energy, Environmental

1 Protection Agency and the state of Idaho are  
2 recommending for cleanup.

3 This meeting represents the 16th time  
4 that we've come out with a proposed plan and asked  
5 for your input. The last time we were here was in  
6 March of 1997 when we were accepting comments on  
7 the Test Reactor Area Comprehensive Remedial  
8 Investigation/Feasibility Study, and I should  
9 mention that the agencies have signed a Record of  
10 Decision on that project, and I have a copy of the  
11 documents at the back of the room. If you would  
12 like a copy, see me during the break, and I'll take  
13 your name and address, and I'll get you a copy.

14 I would like to go over the agenda right  
15 now. Following the introduction, Rick Nieslanik is  
16 going to be giving an overview of the Superfund  
17 processes and how we conduct risk assessments.  
18 Then Margi English from the state of Idaho and  
19 Keith Rose from the EPA will give some brief  
20 comments on their involvement with the Naval  
21 Reactors Facility Comprehensive Investigation.  
22 Following that, Andy Richardson, Mark Hutchison and  
23 Bruce Olenick will give their presentations, and  
24 then we'll have a question-and-answer period where  
25 you can ask questions of the project managers.

1           I should also mention that we do have  
2     some cards at the back of the room. If you would  
3     like to write down your question and give them to  
4     me, I can give them to the project managers.  
5     Following the question-and-answer session, we will  
6     have a public comment session where you can make a  
7     comment for the record. We have a court reporter  
8     here tonight who is recording all portions of this  
9     meeting, and I'll talk about that in a little  
10    while.

11           Then we'll have about a 5- to 10-minute  
12    break, and then we'll come back and discuss the  
13    Argonne National Laboratory-West Comprehensive  
14    Investigation, and our state and EPA  
15    representatives are Daryl Koch, and, once again,  
16    Keith Rose. Greg Bass from DOE-Chicago and Scott  
17    Lee from Argonne will give the presentation, and,  
18    once again, we'll have a question-and-answer  
19    session.

20           I would also like to point out that on  
21    the back of the agenda there is a meeting  
22    evaluation form. Please take a few moments and jot  
23    down your impressions of this meeting. Give them  
24    to me. And this -- we'll use this to shape how our  
25    future meetings are conducted.

1                   With that, I would like introduce  
2 Rick Nieslanik. He's been part of the  
3 Environmental Restoration Program since the  
4 beginning, and he's going to talk about the  
5 Superfund process and risk assessment.

6                   MR. NIESLANIK: I would like to welcome  
7 everyone here tonight. This is a lot bigger  
8 crowd. We've done this presentation at several  
9 locations, and this is by far a bigger crowd and  
10 we're glad to see it. During each of the  
11 presentations tonight, if you can hold your  
12 questions until the end and make some notes or  
13 whatever, that will allow us to move along a little  
14 better and keep us from being here all night.

15                   First of all, I'd like to start out by  
16 giving you an overview of the process that we use.  
17 As you hear the two different projects, the  
18 presentations on the two projects, you're going to  
19 see some things that are very similar about the two  
20 projects and you're going to see some things that  
21 are quite different between the two. The  
22 differences are based on the site-specific  
23 information that the two sites came up with in  
24 their investigations. The similarities are the  
25 process that we use to develop that information and

1 to gather all the data that we need to make a  
2 decision with.

3 These projects are governed by a law  
4 called a Comprehensive Environmental Response  
5 Compensation and Liability Act. It's quite a  
6 mouthful, so we use an acronym, CERCLA, for it.  
7 You'll also hear us use the word Superfund. That's  
8 just another name for that same regulation. The  
9 three agencies that are involved in this project  
10 and cleanup at the INEEL are the Idaho Division of  
11 Environmental Quality, the U.S. EPA and the  
12 U.S. Department of Energy, got together and formed  
13 an agreement called the Federal Facility Agreement  
14 and Consent Order. You'll hear that referred to as  
15 the FFA/CO and also as the agreement later on  
16 tonight.

17 What that agreement lays out is how the  
18 agencies work together to come up with the right  
19 decision for what to clean up and how clean they  
20 have to get things. This agreement also lays out  
21 some steps we take to scope the jobs, to say how  
22 big of a problem do we have at each one of these  
23 individual locations and how are we going to gather  
24 the information we need to assess that. We came up  
25 with what we call a Track 1 and a Track 2 scoping

1 process. And I bring those up because, again,  
2 during the presentations you're going to hear those  
3 terms and I would like to explain what they are.

4 In a Track 1 process, we gathered up all  
5 the existing information that we had on a  
6 particular location. We found a site where we  
7 thought something might have been disposed of. We  
8 went off and we gathered old photographs. We  
9 talked to retired employees, long-term employees.  
10 We looked at operational records and we looked for  
11 all old sampling data that we might have on those  
12 areas, and then we made a decision. One, do we  
13 have enough information to decide we need to clean  
14 it up? Do we have enough information to decide  
15 that we don't need to clean it up, or do we need  
16 more information, do we need more data?

17 If we need more data on a particular  
18 site, then we went to a Track 2 process. A Track 2  
19 process is basically a limited sampling evolution.  
20 Rather than go to a full-blown sampling evolution  
21 on the site, we would take a few samples and then  
22 make the same decision again. Do we have  
23 enough information to proceed? Do we need more  
24 information?

25 At the end of either one of these two

1       scoping evolutions, we could go to a removal  
2       action. A removal action is just what it says. We  
3       could go remove the contamination that was in the  
4       soil, or we could go to an interim action. An  
5       interim action is basically the same thing but a  
6       little bigger. If it was a smaller area, we could  
7       do a removal action. If it's a big area, we would  
8       have to do more paperwork and more investigation as  
9       part of that cleanup. And then finally we could do  
10      a Remedial Investigation/Feasibility Study. That  
11      is a full-blown, large number of samples, big  
12      investigation, and we did that on some individual  
13      sites.

14               What we're talking about tonight, we  
15      call it a Comprehensive Remedial Investigation and  
16      Feasibility Study. Now, the real difference  
17      between these two is simply that in this  
18      comprehensive investigation, we go back and we look  
19      at all these decisions we made before, all of the  
20      scoping decisions that we don't need any more  
21      information or that we cleaned up a site, and we go  
22      back and reevaluate that and decide if that was the  
23      right decision, or if we need to reevaluate that  
24      when it compares to all the other areas on site.

25               Now, what we're talking about tonight

1 are two areas, one called the Naval Reactors  
2 Facility or WAG 8, Waste Area Group 8, and Argonne  
3 National Lab, which is Waste Area Group 9. As you  
4 might guess, 8 and 9, there must be a 1, 2, 3, 4,  
5 5, 6, 7 and also a 10. We're not going to talk  
6 about those. Those are the subjects of other  
7 investigations and there will be public meetings on  
8 several of those over the next few months as well.

9 In all of those individual steps that I  
10 described earlier, there is an element of risk  
11 assessment, and the risk assessment process is  
12 really what we use to make the decision. You  
13 gather all this data and we have to have a  
14 framework, if you will, to evaluate that data to  
15 decide what needs to be cleaned up and what  
16 doesn't. The risk assessment consists of four  
17 basic steps. One, identify the contaminants of  
18 concern. That's all that sampling that I was  
19 talking about and the research that we did and the  
20 existing information, if you will.

21 Then once we've identified those  
22 contaminants, we do two things. We assess the  
23 exposure. How does that contaminant that's in the  
24 ground get to an individual, to a human receptor or  
25 to an ecological receptor, how do they get

1 exposed. And also a toxicity assessment, how toxic  
2 are those chemicals. Each individual chemical,  
3 each individual contaminant that's in the soil, we  
4 went off and look and say, okay, what's the  
5 toxicity of that, and how is that going to affect a  
6 human receptor, and how is that going to affect an  
7 ecological receptor, the animals and the plants.  
8 And after we do that, then we characterize that  
9 risk. We have to tie all that together into one  
10 usable number to help us in that decision that  
11 we're going to make on what to clean up.

12 On the exposure assessment, we look at  
13 the different pathways that we can get  
14 contamination that might be in the soil, to an  
15 exposure to an individual or to an animal, to an  
16 ecological receptor. What we calculate is called  
17 the reasonable maximum exposure. It's not the  
18 maximum that someone could dream up, but it's a  
19 reasonable amount. And it's not the minimum. We  
20 do take into account a lot of different things so  
21 that we get a good conservative, protective  
22 assessment of exposure.

23 These are the different pathways we  
24 looked at. For radioactive constituents, we have  
25 what we call direct exposure. Radioactive elements

1 give off energy and that energy is exposure by  
2 direct irradiation. We look at groundwater. If  
3 there's contaminants in the soil, rainwater,  
4 irrigation, those kind of things can drive that  
5 down to the groundwater. Then it can be pumped out  
6 onto the ground or into a piping system, and we can  
7 have an exposure either to inhalation during a  
8 shower scenario or drinking it, an ingestion  
9 pathway, or even an absorption pathway through your  
10 skin, again, during a shower.

11 We look at dermal exposure. Dermal  
12 exposure is digging in the soil, getting the  
13 contaminants on your hand and having that absorb  
14 through your skin. We look at inhalation. If  
15 there's a contaminant in the soil, it could come up  
16 as a vapor or as dust, get in the air and then you  
17 could breathe that. We look at soil ingestion.  
18 Whether you believe it or not, each one of us  
19 consumes a certain amount of dirt every day, and so  
20 we have a soil ingestion pathway that we have to  
21 look at.

22 Then finally we looked at a crop  
23 ingestion pathway. If a person were to grow  
24 vegetables in contaminated soil, how much of that  
25 contamination would uptake into the plants and how

1 much would we eat, and, therefore, what would our  
2 exposure be. As part of that we also looked at  
3 irrigation with contaminated groundwater. Then  
4 finally, I'll repeat again, we then looked at the  
5 ecological receptor. We looked at mice and birds,  
6 antelope, deer, plants, all the different  
7 ecological receptors we thought would be out there  
8 at the INEEL.

9 Then we assess the toxicity. Two  
10 things we look at when we talk about toxicity,  
11 carcinogenic effects and noncarcinogenic effects.  
12 Those things that cause cancer and those that do  
13 not. Carcinogenic effects, we have what we call a  
14 slope factor. Now, this value is something that's  
15 published for each individual contaminant by the  
16 EPA. It's a compendium, a gathering of all of the  
17 research that's been done, and they come up with  
18 this value. What it represents is that for some  
19 exposure, some dose that we calculated in our  
20 previous step, we can estimate what the response  
21 would be. We represent that response as the risk  
22 of getting one additional case of cancer. It's  
23 presented as a number of one in a million or one in  
24 10,000.

25 Now, we all have a different perception

1 of what's an acceptable risk. A lot of us -- most  
2 of us probably feel that it's a perfectly  
3 acceptable risk to fly in an airplane. Other  
4 people may find that to be an unacceptable risk.  
5 We make risk decisions in our lives every day. We  
6 drive. Do we drive 75 miles an hour? Is that  
7 acceptable? To most people it is if it's on the  
8 highway. Other people, it's not. We make  
9 assessments based on site conditions. We may not  
10 to want to drive 75 miles an hour in the snow, but  
11 we might in dry conditions. Those are personal  
12 risk decisions that we make, but the risk managers,  
13 the agencies involved in these decisions, they need  
14 a guideline by which to make these risk decisions.

15 So they've defined in the National  
16 Contingency Plan, which is one of documents that  
17 comes out of the regulations and I talked about  
18 earlier, the CERCLA, and the National Contingency  
19 Plan says that the acceptable risk range is between  
20 one in 10,000 and one in a million. That is  
21 additional cases of cancer based upon that  
22 calculated exposure.

23 Sometimes you will see that there is a  
24 risk just slightly above or slightly below and the  
25 agencies will have to decide what to do with those,

1       and when they do that, they look at the uncertainty  
2       in all those calculations I've just talked about.  
3       What's the uncertainty in this value, what's the  
4       uncertainty in that reasonable maximum exposure  
5       that I talked about earlier, what are the  
6       uncertainties associated with each those pathways  
7       that I talked about. So there's a lot of  
8       uncertainty assessment that goes into this  
9       decision.

10               The other thing that we looked at is  
11       noncarcinogenic health effects. Now for this one  
12       we use a different value. This is called a  
13       reference dose. For noncarcinogenic effects there  
14       is some level below which there is no observable  
15       adverse effects. We would not expect to see any  
16       adverse effects in those ranges. And, again, this  
17       is based upon all of the research that has been  
18       done around the country and these are published  
19       values by the EPA. So the risk assessors take that  
20       value and compare it to that estimated exposure  
21       that I talked about earlier. Only this time we  
22       come up with a value called a hazard quotient. A  
23       hazard quotient is simply a ratio between that  
24       estimated exposure and this reference dose.

25               So if the estimated exposure and the

1 reference dose are the same, we have a hazard  
2 quotient equal to one. If the estimated exposure  
3 is greater than the reference dose, then the hazard  
4 quotient will be greater than one and vice versa if  
5 it's less than. Again, a hazard quotient of one is  
6 the value that the risk assessors use as a  
7 baseline. Now, if we go above that, does that  
8 necessarily mean that's unacceptable? Well, not  
9 really, because, again, there's some level down  
10 here above the reference dose even where there's no  
11 observable adverse effects. So those are the kind  
12 of things that the agencies will take into account  
13 when they decide what's an acceptable hazard  
14 quotient and, therefore, what needs to be cleaned  
15 up, based on those values.

16 I want you to keep in mind as you listen  
17 to the presentations tonight these things: That  
18 when you look at a decision -- when you've got to  
19 make a decision on what to clean up, you're going  
20 to go to these risk values, what's the hazard  
21 quotient and what's the calculated risk. It takes  
22 into account a lot of things. How a person is  
23 exposed, what the toxicity of each of the chemicals  
24 are.

25 Does anybody have any questions on any

1 of this before I turn this back over to Erik to  
2 introduce the next set of presentations?

3 AUDIENCE MEMBER: Are these numbers --  
4 are these the national numbers or are these the  
5 local DOE numbers?

6 MR. NIESLANIK: The question was, are  
7 these local values or national EPA values. The  
8 reference dose and the slope factors are nationally  
9 published by the EPA. They are in a series of  
10 documents, the health effects assessment tables  
11 that you can pull off -- you can get them off the  
12 Internet now.

13 AUDIENCE MEMBER: It's a standard?

14 MR. NIESLANIK: It's a standard value.

15 AUDIENCE MEMBER: Back to your previous  
16 slide, I wasn't sure I understood it.

17 MR. NIESLANIK: What I'm talking about  
18 here is a slope factor.

19 AUDIENCE MEMBER: The one before this.  
20 I'm sorry. The carcinogenic.

21 MR. NIESLANIK: The important thing here  
22 is the difference between this and the one I talked  
23 about just a minute ago. This slope factor, if you  
24 notice for any increase in dose, there is an  
25 increase in response -- in the effect, whereas the

1       other one, there's a level below which there is no  
2       effect for low doses.

3               AUDIENCE MEMBER:   Isn't that true for  
4       radiation exposures too?

5               MR. NIESLANIK:   Yes.   This is the way  
6       that the EPA risk calculations go:   They consider  
7       radiation, radionuclides as carcinogenic so there  
8       is a slope factor for --

9               AUDIENCE MEMBER:   The other one had a  
10       threshold sort of thing, and you don't have one  
11       here.   You have a linear dose.

12              MR. NIESLANIK:   Right.   That is the way  
13       that these calculations assess radiation.   They use  
14       this approach, which is a little different than  
15       just calculating the millirem that a person would  
16       receive.   It is based on and makes the assumption  
17       that any amount of exposure does result in some  
18       response, however small that response may be.

19              AUDIENCE MEMBER:   The question in my  
20       mind is, I've seen information that indicated that  
21       below some threshold you don't have a linear  
22       response.

23              MR. NIESLANIK:   There is a lot of  
24       uncertainty.   Again, I talked about the  
25       uncertainty.   There's a lot of uncertainty in these

1 slope factors. They are based on a lot of research  
2 and they're based on the best information that the  
3 EPA has available. But, again, you've got to keep  
4 in mind what we're trying to do with this data.  
5 We're not trying to determine how many people are  
6 going to get cancer. What we're trying to do is  
7 come up with this value that the risk assessors,  
8 that the agencies are going to use to make a  
9 decision on what to clean up, and this framework  
10 that we're using is prescribed, and it allows us to  
11 compare radioactive exposure to nonradioactive  
12 carcinogens, and so it's more a matter of giving us  
13 the data we need to make a decision, not estimating  
14 how many people are going to get cancer.

15 Any other questions? Okay.

16 MR. SIMPSON: To help out the court  
17 reporter, we're going to start using the  
18 microphone. I feel like a Congressman. At this  
19 time, I would like to introduce Margi English, who  
20 is with the state of Idaho, Department of Health  
21 and Welfare, Division of Environmental Quality, and  
22 she was a project manager for Waste Area Group 8,  
23 and also Keith Rose who is with the EPA's Region 10  
24 office in Seattle. They're going to make a few  
25 statements.

1 MS. ENGLISH: I want to welcome you all  
2 here. It's really good to see so many people come  
3 out and have interest in what we're doing on the  
4 INEEL. Can everybody hear me? It's hard for me to  
5 tell up here if the microphone is working.

6 I've worked together with EPA and  
7 the Naval Reactors Facility for the past  
8 five-and-a-half years addressing potential past  
9 contamination release sites at the Naval Reactors  
10 Facility. And during that time we've evaluated  
11 certain sites -- fully evaluated certain sites,  
12 made some remedial decisions. We've conducted a  
13 couple of removal actions, and we've successfully  
14 conducted a remedial action for several existing  
15 landfills on the NRF.

16 We're real happy to say that those  
17 previous cleanup actions have been conducted  
18 within -- on schedule and within budget, and at  
19 this point in time in the process, we're turning  
20 our attention to the remainder of the sites on the  
21 NRF, as well as looking at all of those previous  
22 decisions in a more cumulative, overall aspect, and  
23 some of the later presenters will explain that in  
24 more detail.

25 Throughout the process of this final

1 remedial investigation, the state has participated  
2 in development of the investigation and scoping the  
3 investigation. We've worked to develop the risk  
4 assessment once we have gotten data. Also the  
5 state, together with the NRF and our EPA  
6 counterparts, have developed and screened potential  
7 cleanup remedies for the site, as well as fully  
8 participated in developing and writing the proposed  
9 plan that you all have copies of.

10 Where we are right now is, we're at a  
11 point in the process where we really welcome and  
12 encourage public participation into the remedial  
13 decision selection. I want to emphasize tonight  
14 that even though the proposed plan identifies a  
15 preferred cleanup alternative, the agencies have  
16 not yet selected a cleanup remedy to implement, so  
17 therefore, it's very important and I want to  
18 emphasize to you all that you should comment on all  
19 of the remedial alternatives in the proposed plan,  
20 not just on the preferred alternative, and also, if  
21 you feel that there are any options that the  
22 agencies have not considered, we would really  
23 welcome your input on that.

24 We will take your comments and your  
25 opinions and we'll then use those to help us select

1 the final cleanup remedy for the sites that you'll  
2 hear about tonight, and those final remedies will  
3 be documented in a Record of Decision that will be  
4 finalized later this year.

5 Tonight, if you have any questions about  
6 the sites or about the remedy selection process,  
7 please don't hesitate to ask. We will be very  
8 happy to answer your questions. With that, I'm  
9 going to turn this over to my EPA counterpart,  
10 Keith Rose.

11 MR. ROSE: Good evening. My name is  
12 Keith Rose. I'm EPA's project manager for the  
13 Nuclear Reactors Facility at INEEL. Myself and my  
14 fellow project managers at EPA, who were prior  
15 managers on this project, to myself, have reviewed  
16 and approved the remedial investigation and  
17 feasibility study for the NRF facility, and I have  
18 also reviewed and concurred on the proposed plan  
19 for NRF. Specifically concurred with -- or EPA  
20 has concurred on the selection of a preferred  
21 alternative, which you are going to hear about  
22 later on for NRF.

23 This -- our concurrence on the preferred  
24 alternative is based on seven of the nine criteria  
25 that EPA uses to select an alternative, a remedial

1 alternative. These seven criteria include such  
2 things as protection of human health in the  
3 environment, meeting environmental regulations,  
4 short-term and long-term effectiveness and  
5 implementability and cost. The two remaining  
6 criteria, which we are looking for input on, are  
7 state acceptance of the preferred remedy and  
8 community acceptance of the preferred remedy and  
9 any other comments on any other of the alternatives  
10 which were proposed. So our final decision would  
11 be based on those two final criteria along with the  
12 seven other criteria.

13 Our final decision will be embodied in a  
14 Record of Decision as Margi referred to, which will  
15 be issued later on this year. I will be available  
16 later on for questions or comments after the  
17 presentation. Thank you.

18 MR. SIMPSON: I've noticed that only a  
19 fraction of people who are here tonight have signed  
20 in. When we have a break, please do so. At this  
21 time, I would like to introduce Andy Richardson.  
22 Andy is with the DOE Naval Reactors Branch, and he  
23 will talk a little bit about the Naval Reactors  
24 Facility background and this comprehensive  
25 investigation.

1                   MR. RICHARDSON: Good evening. Can  
2 everybody hear okay? As Erik said, my name is Andy  
3 Richardson. I work in the local Naval Reactors  
4 Idaho branch office out at the Naval Reactors  
5 Facility. Actually my office is in that building  
6 right there. What I want to talk to you about  
7 briefly this evening is a little bit of the history  
8 of the Naval Reactors Facility, some of the  
9 activities that took place out there and how some  
10 of those activities got us to the point where we  
11 think we need to do some cleanup action.

12                   Back in the late 1940s the decision was  
13 made that the United States was going to go build  
14 nuclear-powered submarines. That job was given to  
15 then Captain Rickover, said go out, build us a  
16 nuclear-powered submarine, do it right, let us know  
17 when it's done. That's essentially what Captain  
18 Rickover did. He did a lot of research, came out  
19 to Idaho and what was then called the National  
20 Reactor Testing Station in 1951, established the  
21 Naval Reactors Facility. It was much smaller than  
22 this in 1951.

23                   They commenced construction on the S1W  
24 prototype. That was the prototype plant, test  
25 plant, if you will, for the submarine Nautilus,

1     which I'm sure most of you all have heard of, the  
2     first nuclear-powered submarine. As things moved  
3     along more quickly in the '50s than they do in the  
4     '90s, by March of 1953 the S1W prototype was  
5     actually operating at power, proving that you could  
6     use nuclear power to push submarines through the  
7     water.

8                 Consistent with the technology and use  
9     back in the '50s, part of the S1W prototype complex  
10    was a system that allowed for discharge of  
11    radioactive water from the prototype plant out to  
12    originally what was called a tile drain field. A  
13    tile drain field is not much more then a relatively  
14    large concrete pipe buried about 10 feet under the  
15    surface of the ground. At that end of the pipe you  
16    have a bunch of holes. Water goes out, not  
17    surprisingly leaks out the holes that are  
18    intentionally in the pipe and into the soil. The  
19    idea being that the contaminants that were in the  
20    radioactive water would be caught up in the soil  
21    and immobilized.

22                That actually worked pretty well,  
23    because by 1955 this drain field wasn't working as  
24    well or it wasn't draining as well as it had  
25    originally, and the decision was made to expand

1       this discharge point to what's called the S1W  
2       leaching pit. The concept was the same. You  
3       discharged some of the radioactive water out to the  
4       soil, with the contaminants getting entrained in  
5       the soil.

6               About the same time, mid-'50s, a couple  
7       of other major developments took place at the Naval  
8       Reactors Facility. First being the decision that  
9       not only were nuclear submarines a good idea to  
10      have, but it certainly seemed that a nuclear  
11      aircraft carrier would be good thing to have. So  
12      the program, in 1957, placed the A1W prototype in  
13      operation. That was the prototype for the aircraft  
14      carrier Enterprise which, in fact, is still out  
15      operating today, the first nuclear powered aircraft  
16      carrier.

17             Also in 1957, 1958 time frame, the Navy  
18      built the Expanded Core Facility, also in  
19      operation. This facility, now that we've had some  
20      operating reactors for five years or so, was built  
21      so we could take those reactor cores that had been  
22      in use, bring them to this facility and inspect  
23      those cores, make sure that those cores, in fact,  
24      performed the way that they were designed to  
25      perform from a corrosion standpoint, from a

1 strength standpoint, make sure that they did what  
2 we thought that they were going to do.

3           Along with these two facilities,  
4 obviously there became other opportunities to  
5 discharge some of the water. For the A1W reactor  
6 plant, we built on the west side of the facility  
7 another leaching bed similar to the ones that we  
8 had used for the S1W facility. This was another  
9 receiving point for radioactive water discharges  
10 from the A1W prototype. Similarly, the Expanded  
11 Core Facility had radioactive liquid discharges.  
12 Those were, in some cases, sent over to the S1W.  
13 It's what we call this discharge complex if you  
14 will.

15           So that gets us through the late '50s.  
16 We have two operating reactor plants. We were  
17 conducting research and development on propulsion  
18 systems for ships. We were performing inspections  
19 and research in development on materials so we can  
20 build better cores. About the mid-1960s we decided  
21 to build yet another prototype reactor plant. This  
22 was called the S5G Reactor Plant that was a  
23 significant upgrade in the technology. It put us  
24 in a position where we could run a reactor plant  
25 that did not require pumps to move cooling water

1 through the actual reactor.

2 That provided a couple significant  
3 advantages to the Navy. It let us build submarines  
4 that were much quieter because you didn't have to  
5 have these big pumps moving water around. It also  
6 provided you an inherently even more safe design  
7 than you already had because in the event -- if you  
8 don't have to have the pumps to move the cooling  
9 water, you're always assured that it's going to  
10 move through the core and remove any heat that's  
11 there.

12 In this same time frame, in the middle  
13 1950s, based on lessons we learned from the  
14 operation of some of this discharge points a  
15 program -- came to the conclusion that it was a  
16 smarter idea not to discharge these liquids out to  
17 the environment, and we started working in the late  
18 1950s, on systems that we could use to recycle,  
19 reuse that radioactive water. Okay. And we  
20 started placing some of those early systems in use  
21 in 1972 and, by 1979, in fact, had ceased all  
22 discharges of these radioactive liquids to the  
23 environment.

24 So that essentially leaves us -- well,  
25 that put us in a position by the late '70s where

1       you had the three operating plants and the Expanded  
2       Core Facility. Starting in 1989 these three  
3       prototype reactor plants were sequentially shut  
4       down, S1W in 1989, A1W in 1994 and this S5G in  
5       1995. Currently, the Expanded Core Facility is the  
6       main operating facility out there at NRF.

7               So getting back to this idea of the  
8       Comprehensive Remedial Investigation that Rick  
9       talked about earlier, over the last five years or  
10      so we've done a lot of investigation all over the  
11      site. But primarily due to these radioactive  
12      discharge points, we feel that the sites of real  
13      concern, the sites that we really think we need to  
14      go off and take some sort of cleanup action on are  
15      the nine sites that are shown on this picture.

16             A couple of my counterparts will be  
17      coming up. They will go into a little more detail  
18      on these particular sites, and if there aren't any  
19      other questions on the historical aspect, I would  
20      like to turn this over to Mark Hutchison who is one  
21      of the primary engineers throughout this entire  
22      investigation process for the Naval Reactors  
23      Facility.

24             AUDIENCE MEMBER: How was the  
25      record-keeping for the type of waste that was

1 discharged -- I know that there was radioactive,  
2 but maybe possibly other things. How was the  
3 record-keeping for NRF?

4 MR. RICHARDSON: The record-keeping at  
5 NRF actually has been quite good. For instance, if  
6 you go to this warehouse building, you can still go  
7 and find what were chemicals which routinely are a  
8 problem out at the INEEL as a whole. You can find  
9 what are called traveling requisition cards that  
10 show every chemical that was bought for use at NRF  
11 and how much of it was bought and when it was  
12 bought, going all the way back to 1951. The  
13 radioactive discharge records are, in fact,  
14 excellent. Any other questions? Okay. I would  
15 like to turn this over to Mark.

16 MR. HUTCHISON: Good evening,  
17 everybody. I hope you will bear with me. I'm  
18 munching on a cold tablet and hopefully it doesn't  
19 come flying out while I'm talking. I'd like to  
20 begin by briefly going over the CERCLA process at  
21 the Naval Reactors Facility. We had 71 identified  
22 sites at the Naval Reactors Facility that required  
23 us to go off and do some kind of investigation  
24 assessment, evaluations. Those are the kind of  
25 words that we use to look at these sites and

1 evaluate them. Ten of those sites were included in  
2 a previous Record of Decision. The Record of  
3 Decision included three remedial actions where we  
4 placed landfill covers over three landfill areas.

5 We had 43 other sites that were looked  
6 at through a Track 1, Track 2 type of investigation  
7 that Rick discussed earlier. The conclusion of  
8 these investigations were we did not require any  
9 further investigation of them. And that leaves us  
10 with 18 other individual site assessments that were  
11 included in this comprehensive remedial  
12 investigation and feasibility study, which I'll try  
13 to call "the study" from now on. This  
14 comprehensive study looked at these 18 sites and  
15 did a cumulative assessment of all the identified  
16 sites at the Naval Reactors Facility and came to  
17 the conclusion like Andy was talking about earlier,  
18 that we have these nine sites of concern that we  
19 need to go off and do some action with.

20 That brings us to the point right now of  
21 the public comment where we receive the public  
22 comments on our proposed and preferred actions, and  
23 later on we will go into a comprehensive Record of  
24 Decision where we'll have a responsiveness from  
25 this summary which will address the public comments

1       that we receive during this public comment period.  
2       On down the road we'll have a remedial design,  
3       remedial action phase where we actually go into  
4       implementation of whatever actions are chosen. It  
5       includes some monitoring, and even further down the  
6       road is what we call a five-year review period  
7       where we actually go back and look at the  
8       effectiveness of the actions that have been  
9       selected.

10               The comprehensive study involves five  
11       primary tasks. We did this individual assessment  
12       of 18 potential radiological sites. It included a  
13       cumulative assessment of all 71 of the identified  
14       sites at the Naval Reactors Facility. We developed  
15       what we call remedial action objectives. We  
16       developed and evaluated various remedial action  
17       alternatives, and then finally there was a  
18       selection of a preferred alternative.

19               I'm going to talk about the first two of  
20       these tasks. The first one was the individual site  
21       assessments. We had 18 potential radiological  
22       sites that we had to go off and look at the history  
23       of them and gather as much information on the  
24       discharges to them, pull out old documents,  
25       anything that we could find that had information on

1       these 18 sites. This led into a sampling phase  
2       where we collected surface and subsurface soil  
3       samples and groundwater samples from a groundwater  
4       monitoring network that surrounds the perimeter of  
5       the Naval Reactors Facility. All this information  
6       was brought in together and used in a human health  
7       risk assessment for each of the sites.

8               The conclusion of this human health risk  
9       assessment was, we had these nine sites of  
10      concern. The cumulative assessment of this  
11      comprehensive study evaluated the 71 sites that we  
12      had identified at the Naval Reactors Facility and  
13      looked at the potential additive effects of all  
14      these sites on a potential receptor. The  
15      conclusion of our comprehensive cumulative health  
16      assessment was we did not identify any additional  
17      sites of concerns, other than the ones that we  
18      found during our individual site assessment.

19             We performed an ecological risk  
20      assessment that evaluated potential impact to  
21      environmental receptors. This ecological risk  
22      assessment concluded that the steps we take to be  
23      protective of human health will also be protective  
24      of the environment, and so there was no additional  
25      actions that needed to be taken as far as the

1 environmental receptors go. We also included a  
2 hydrogeological study which assess the potential  
3 impacts to groundwater. The information that we  
4 got from this hydrogeologic study was used for the  
5 human health risk assessments and evaluation of  
6 some of the pathways that we had there, the  
7 groundwater ingestion, the fruit, crop irrigation  
8 ingestion pathway.

9 The cumulative assessment as a whole  
10 came to the conclusion that the sites we identified  
11 during our individual site assessments were the  
12 primary sites of concern and that's the nine sites  
13 that we had discussed earlier.

14 The human health scenarios that we  
15 looked at during our risk assessment included a  
16 residential scenario and an occupational scenario.  
17 The residential scenario, we looked at a 30-year  
18 future resident. We looked at a 100-year future  
19 resident. The occupational scenario, we looked at  
20 a current worker out there right now, a 30-year  
21 future worker. We have highlighted the 100-year  
22 future resident, and that is our primary scenario  
23 of concern. Part of the reason for that is there  
24 is an assumption made that there is going to be  
25 some type of institutional or governmental control

1 of the area for the next 100 years. You're not  
2 going to have a resident building a home or  
3 establishing a residence out at that site within  
4 the next 100 years.

5 For the occupational scenario we have  
6 controls in place. We have procedures in place  
7 that protect the workers, that keep the workers  
8 from digging into these areas and becoming exposed  
9 to some of the contaminants that are there. The  
10 risk assessment that we performed identified nine  
11 contaminants of concern. We had eight  
12 radionuclides and one inorganic metal lead. The  
13 ones that are highlighted, cesium-137 and  
14 strontium-90, were by far our risk drivers. They  
15 were the ones that showed the most risk for these  
16 sites. We had one site where we detected lead  
17 above the EPA screening level for a recommended  
18 cleanup.

19 This slide here is a bar graph that  
20 shows these sites of concerns and where they fell  
21 as far as the risk goes. This is that one in  
22 10,000 level that Rick had talked about earlier.  
23 Seven of our nine sites are above that level. It's  
24 obvious that they are human health concerns and  
25 that's why they are sites of concern to us.

1       There's two other sites. One here, the A1W/S1W  
2       radioactive line which is actually below one in  
3       10,000, but there's some uncertainty associated  
4       with that line. It's an underground line that has  
5       leaked in the past, and there is a potential that  
6       contaminants are there that would cause the human  
7       health risk to be above the one in 10,000 level.

8               The S1W retention basins are concrete  
9       structures that held water at one time. There's  
10      reason to believe, historical evidence, that these  
11      basins leaked at one time and the potential for  
12      soil underneath the basins above levels that would  
13      be a human health concern. And we had 52 other  
14      sites that had risks in or below this range or even  
15      no risk at all because there was not a source  
16      present. These 52 sites are going to be  
17      recommended as no additional action, and Bruce will  
18      talk about those a little bit later.

19             At this point, I'm going to turn it over  
20      to Bruce Olenick who will continue on with the  
21      presentation.

22             MR. OLENICK: Okay. Let me review.  
23      Just take a moment to go back and review real  
24      quickly what we've been talking about. Andy went  
25      through some of the history of the discharges of

1 the facility, the three different locations of the  
2 reactor power plants and the types of leaching  
3 fields that we had at the facility. Mark went  
4 through and discussed some of the risks involved  
5 and how we calculated those risks, essentially for  
6 each of those nine sites of concern that are  
7 located on this chart over here. Given those nine  
8 sites of concern, the next step in this process is  
9 to say, now what? How do we go about cleaning up  
10 these sites?

11 Well, the first step, in order to do  
12 that is to create remedial action objectives. All  
13 those are is just a fancy-name for goal in order to  
14 achieve the types of cleanup levels that you  
15 would -- you're going into this to accomplish.  
16 These goals can be summarized or divided into two  
17 basic groups, the first being protection of human  
18 health. The first goal is to prevent the direct  
19 exposure or the ingestion of soil or food crops  
20 that were grown on these individual sites 100 years  
21 in the future for the 100-year future residential  
22 scenario that would result in any excess cancer  
23 risk of that one in 10,000 to one in one million  
24 range.

25 Another goal or remedial action

1 objective is to prevent any exposure contaminated  
2 with lead at that lead screening level at 400 ppm  
3 recommended by the EPA for cleanup. On the  
4 right-hand side of this, note that those  
5 contaminants of concern that Mark mentioned  
6 earlier, cesium-137 and strontium-90, these levels  
7 right here are the levels in which we will go out  
8 and clean up those nine sites of concern. Those  
9 are based upon 100 years in the future. Anything  
10 that is left above those individual limits will  
11 present a potential risk to a human receptor 100  
12 years in the future. Anything below that would be  
13 acceptable risk. And then the lead, once again, is  
14 that recommended EPA screening level for cleanup at  
15 400 ppm.

16           Given that, there's also goals that we  
17 establish for the protection of ecological  
18 receptors, as mentioned earlier. The primary goal  
19 is to prevent the erosion or intrusion by plant or  
20 animal species into these nine sites. In addition  
21 to that is to prevent any type of exposure to these  
22 ecological receptors to the contaminants of concern  
23 located at these sites.

24           Through this process we evaluated many  
25 different alternatives to go off and address each

1 of these nine sites. Going through that process  
2 we've narrowed it down to four alternatives that  
3 we've selected for full evaluation. The first one  
4 being the baseline scenario recommended by the EPA  
5 is a no-action scenario. That particular action  
6 involves doing nothing, having no controls in place  
7 and doing no additional monitoring than what the  
8 facility currently does.

9 The second proposed response action is  
10 called limited action. That action invokes  
11 long-term monitoring and also institutes control  
12 over the control period of 100 years. In other  
13 words, fencing, barriers, signs, those type of  
14 things to limit access to those nine sites of  
15 concern.

16 The third action that was considered is  
17 called limited excavation, disposal and  
18 containment. Essentially what that is, is kind of  
19 a fancy name for consolidation of those nine areas  
20 into essentially two areas. What that would  
21 involve is just building on number two. Note that  
22 long-term monitoring would still be in place.  
23 Institutional controls would be invoked and then  
24 consolidating the soil of six of the smaller sites  
25 at the Naval Reactors Facility into two of the

1 larger sites. That soil consolidation, once  
2 accomplished, two engineered caps would be built  
3 over both the S1W leaching bed complex and the A1W  
4 leaching bed complex. The purpose being to -- once  
5 again, remember those goals we talked about -- to  
6 eliminate intrusion by plant or animal species into  
7 those areas of concern.

8 The last proposed action that we  
9 evaluated was a complete excavation and removal,  
10 taking all the soil volume for those nine sites,  
11 packaging it up and disposing of it at a location  
12 off the Naval Reactors Facility itself. For that  
13 particular alternative, no long-term monitoring  
14 or controls are necessary because all the  
15 contamination is actually moved off site. So given  
16 that -- I think Keith, a little earlier, mentioned  
17 the nine criteria that the EPA uses now to judge  
18 the difference between those four proposed  
19 actions.

20 These nine criteria -- and I'll  
21 summarize them once again very briefly -- the first  
22 two being threshold criteria that essentially you  
23 look at those two and see how those four actions or  
24 proposed actions measure up, protection of human  
25 health and how they comply with all applicable

1 laws. The next two, long-term effectiveness and  
2 short-term effectiveness were looked at. Long-term  
3 effectiveness would be how well does that  
4 alternative actually clean up the site over the  
5 long haul. And short-term effectiveness: how good  
6 is it at protecting workers as they are performing  
7 that action.

8 Treatment is another evaluation criteria  
9 that's used. Although, if you notice, none of  
10 those four alternatives had treatment as a selected  
11 option, so that was eliminated. Ease of  
12 implementation: how well can we do this and how  
13 easy can we perform each of these actions. And  
14 finally, cost. How much do these cost? What's the  
15 bottom line to the taxpayer and how fiscally  
16 responsible can we be? The last two, state  
17 acceptance and public acceptance, again, Keith  
18 mentioned that briefly. The primary emphasis here  
19 is this meeting. This meeting is seeking your  
20 input here into these proposed alternatives.

21 Now, if we compare those four  
22 alternatives, if we break them down into their  
23 component parts, notice that Alternative 1, the  
24 no-action alternative was screened out based on  
25 that evaluation criteria because it was not

1 protective of human health and the environment.  
2 That left us with three. And if you notice, I used  
3 kind of some buzz words here to keep them fresh in  
4 your mind so you can identify back again to that  
5 earlier slide. Alternative 2, fence and  
6 monitoring. Alternative 3, consolidate and  
7 monitor. And finally Alternative 4, complete  
8 removal of the contamination.

9 If we look at those criteria that we  
10 mentioned earlier, here on the left-hand side of  
11 the slide, kind of a consumer report table here so  
12 you can kind of visually see what's going on,  
13 notice Alternatives 3 and 4 best meet protection of  
14 human health and complying with all applicable  
15 laws. Note that Alternative 2 does not meet any of  
16 that. It's just less efficient in meeting those  
17 particular criteria than the other two  
18 alternatives. Long-term effectiveness, obviously a  
19 complete removal of all contamination at the Naval  
20 Reactors Facility from those nine sites of concern  
21 is the best mode of operation when it comes to  
22 long-term effectiveness. And then obviously, the  
23 next two, doing actually nothing is the least  
24 effective.

25 Short-term effectiveness is the inverse

1 of that. Obviously, excavating all nine sites at  
2 the Naval Reactors Facility would require lots of  
3 worker exposure. That would be the least  
4 effective. Whereas doing nothing, again, wouldn't  
5 expose the local worker to the types of exposures  
6 encountered in Alternative 4. Implementability,  
7 once again, very similar to short-term  
8 effectiveness, obviously doing nothing is the  
9 easiest, and complete removal is the most  
10 difficult, which brings us to cost. Cost is kind  
11 of self-explanatory.

12 I just wanted to briefly mention that,  
13 again, most of this is monitoring cost over a  
14 30-year period. \$9 million is, again, that  
15 consolidation of six of the smaller sites into two  
16 of the larger ones. Then finally, the increased  
17 cost here is actually excavating all nine sites,  
18 the last two being the largest sites that would  
19 have to be excavated and moved off site, so hence,  
20 the increase in cost there. So looking at that  
21 list, Alternative 3 was chosen as the preferred  
22 alternative based on all seven criteria weighed  
23 against one another and looking at what is the best  
24 one that we can accomplish both cost-wise,  
25 short-term effectiveness, all those different

1 criteria that we used.

2 Alternative 3, what it does is  
3 essentially take the six sites located around the  
4 S1W complex there, take the volume of soil, the  
5 maximum we calculated for contamination of those  
6 areas, and place it into what is known as the S1W  
7 leaching bed. The S1W leaching bed has a volume of  
8 about 90,000 cubic feet. Those six sites, the  
9 maximum amount of contaminated soil we have  
10 calculated is about 60,000 cubic feet. That volume  
11 fits nicely in there with another, approximately,  
12 third to go for any contingency built in.

13 But those six sites once placed in the  
14 S1W leaching beds with -- an engineered cap would  
15 be developed over the top of both the S1W leaching  
16 pit and leaching beds because of their close  
17 proximity to one another, as well as an engineered  
18 cap placed over the A1W leaching bed on the west  
19 side of the facility. What that does is reduce the  
20 footprint, the contamination footprint at NRF, into  
21 two sites that can be easily monitored and  
22 tracked.

23 Finally, institutional controls and  
24 long-term monitoring would be invoked to prevent  
25 any type of human intervention into those areas,

1       and also, like Mark mentioned earlier, we have a  
2       network of monitoring wells around the facility,  
3       kind of encircled on the south end of the facility,  
4       to monitor and ensure that these remedies remain  
5       protective of the environment and human health.

6               Just a quick example of the types of  
7       engineered caps we're considering. The next phase  
8       of this, after the Record of Decision, after  
9       getting your input and concerns -- and looking at  
10      if this alternative is the selected alternative,  
11      those caps are evaluated on their effectiveness and  
12      how well they can contain that material. Notice  
13      that on top, 24 inch nominal rip rap which are  
14      large boulders partly due to prevent, again, that  
15      intrusion from plant and animal species in those  
16      nine sites of concern.

17             So basically in summary, going back to  
18      the very beginning now, through all the risk  
19      assessment we have identified nine sites of concern  
20      at the Naval Reactors Facility based on human  
21      health concerns. Those nine sites require some  
22      sort of remedial action. We did a cumulative  
23      assessment that didn't identify any added effects  
24      from all those 71 sites we had at the facility that  
25      we evaluated. We've identified four remedial

1        action alternatives. We've evaluated those  
2        alternatives compared to that criteria of nine that  
3        we mentioned earlier. Selected the third  
4        alternative as the preferred alternative which  
5        essentially is excavating six of the smaller sites,  
6        consolidating it in a larger site and building  
7        engineered caps over two of the sites, and then a  
8        long-term monitoring program.

9                In addition to that, 52 sites are  
10       recommended as requiring no additional action.  
11       That's basically split. Eleven sites still have a  
12       source present but located deep underground.  
13       Eleven of those sites will be continually rolled  
14       into the process and reviewed on that five-year  
15       review process to ensure that the actions we  
16       perform remain protective of the environment. The  
17       other 41 sites are no action, meaning that there's  
18       no source present, rubble piles that we determined  
19       over time that there isn't any risk there at all.

20               Which brings us to the last portion of  
21       this. Understanding your concerns, your comments  
22       and answer any questions that you have. This is  
23       six-year process of digging through lots of data,  
24       interviewing old employees, doing a lot of  
25       different things. It's integral to our study that

1 we get your input. We encourage that you have oral  
2 and written comments. On the back of the proposed  
3 plan that you have in front of you, there is a  
4 sheet that you can fill out and drop in the mail to  
5 us.

6 The comment period ends February 10th,  
7 1998. Once we assimilate all those comments, we  
8 create a Responsiveness Summary in the Record of  
9 Decision which finalizes the plan that we're going  
10 to go use to clean up the Naval Reactors Facility,  
11 and that will be accomplished in the summer of  
12 1998. Finally, like I mentioned earlier, we go  
13 into the remedial design, remedial action phase  
14 that will begin in the fall of 1998.

15 So with that, let me turn it back over  
16 to Andy Richardson so he can field and sort out  
17 questions for you folks.

18 MR. RICHARDSON: You all look like  
19 you're just thoroughly engrossed here. I don't see  
20 a lot of burning questions on people's lips, but  
21 I'm sure there's some. Beatrice, you had your hand  
22 up.

23 AUDIENCE MEMBER: Could you explain how  
24 you decide when to do a qualitative risk assessment  
25 versus a quantitative assessment.

1                   MR. RICHARDSON: The question was how  
2 the decision is made, whether to do what's called a  
3 qualitative risk assessment versus a quantitative  
4 risk assessment. I guess maybe a quick definition  
5 of qualitative risk assessment is one that doesn't  
6 necessarily crunch numbers down so what you have  
7 here is some number of value after some decimal  
8 point that you can use to compare to some other  
9 number. That would be a quantitative.

10                   A qualitative is a more general process  
11 where you take a relative look as a risk manager.  
12 You make a decision on do you think that the  
13 information that you have at hand is sufficient to  
14 reasonably make a decision on a proposed course of  
15 action without going forward and doing a lot more  
16 sampling, a lot more analysis, and I guess, from my  
17 perspective, the best answer to that is, it is  
18 strictly a management decision, based on what are  
19 the uncertainties in the analysis that we have,  
20 would the additional sampling analysis and number  
21 crunching provide us any more useful information  
22 that we, as managers, see as something that might,  
23 in fact, have an impact on the decision.

24                   So it's a fairly subjective look to a  
25 point. That's what it gets down to, management

1 decisions on how good is the data that you have,  
2 how much more precision will add to the quality of  
3 your decision. Do you have anything you would like  
4 to add to that?

5 MR. OLENICK: Maybe to give you an  
6 analogy, when you do a qualitative risk assessment,  
7 it's like comparing -- when you've got numbers and  
8 you collect data -- qualitative works real well.  
9 When you collect data and you got a number like  
10 52.9 and 59, you do a T-test or some type of  
11 statistical test to show there's either a  
12 difference or similarity between those two  
13 numbers. In a lot of instances, when you've got a  
14 number like a one hundred and one and the data is  
15 tight, you don't have to go through all that number  
16 crunching. Just say, well, qualitatively,  
17 obviously a hundred is different than one. It is a  
18 decision. It is a risk management decision, but  
19 that kind of puts it in perspective. You don't  
20 waste a lot of time going through and spending a  
21 lot of money when something is relatively obvious.

22 MR. ROSE: Keith Rose with EPA. I just  
23 wanted to add that the -- correct me if I'm not  
24 correct here, Andy. The Track 1 assessment is very  
25 qualitative. It doesn't involve a detailed risk

1 assessment, whereas the Track 2 and the assessment  
2 done during the baseline risk assessment is very  
3 quantitative.

4 MR. RICHARDSON: That's correct.

5 MR. ROSE: That is a distinction in the  
6 process. Earlier on, the data is adequate. Often  
7 a decision will be made qualitatively without doing  
8 a detailed assessment, but as you get further into  
9 your assessment, Track 2 and the baseline risk  
10 assessment, it gets more quantitative.

11 MR. RICHARDSON: Do you have a  
12 question?

13 AUDIENCE MEMBER: I know that you do a  
14 lot of sampling on the groundwater. Is the  
15 modeling part of the remedial investigation or any  
16 other as far as the movement of the groundwater,  
17 and when it's going to be down to a certain level,  
18 that it's really not too seriously harmful to the  
19 human health within this 100-year scenario?

20 MR. RICHARDSON: The question is what's  
21 the role -- and correct me if I'm wrong. What's  
22 the role of groundwater modeling in this Remedial  
23 Investigation/Feasibility Study? What sort of  
24 modeling is done? Does it get carried in the risk  
25 assessment? Is that it?

1 AUDIENCE MEMBER: Yes.

2 MR. RICHARDSON: The answer is, yes. We  
3 do -- an integral part of the remedial  
4 investigation is the hydrogeologic study, which is  
5 a fairly detailed study of what does happen to  
6 water -- to groundwater around the Naval Reactors  
7 site and Naval Reactors Facility. We take a look  
8 at the contaminants of concern. You do, in fact,  
9 model those. You look at the different factors  
10 that affect transport. You do a fairly detailed  
11 characterization of the strata underneath the  
12 facility and how that impacts the transport of the  
13 contaminants and their potential for getting into  
14 the groundwater. In fact, the results of that  
15 groundwater modeling for the remedial investigation  
16 for the Naval Reactors Facility shows that the  
17 groundwater path is not, in fact, a pathway of  
18 concern for our contaminants. Did you want to add  
19 anything?

20 AUDIENCE MEMBER: So, like, within the  
21 hundred-year period then, basically -- as long as  
22 the soil is contained and capped and there's really  
23 actually no more leaching going on.

24 MR. OLENICK: The model did assume  
25 leaching, though. Even though there won't be any,

1       it assumed that. So we used worst-case scenarios  
2       when we did models, but, yes.

3               MR. RICHARDSON: This is one point that  
4       brings up some of the conservatism. For example,  
5       with your groundwater modeling, as Bruce just said,  
6       you assume that you will get some leaching from the  
7       material, but when you do your plant uptake  
8       modeling for your ecological part of the  
9       assessment, you assume all those contaminants are  
10      still there available for the plants. So in one  
11      case you assume that it's leaching away and in the  
12      other scenario you assume that it's all there and  
13      available for uptake by plants. That goes to the  
14      conservatism of the analysis.

15             AUDIENCE MEMBER: I'm a little confused  
16      on the drivers cleaning this up. As I understand  
17      what you presented, you're going to move six of  
18      your sites to the remaining two larger ones and  
19      keep all of the contaminated soil on site. What  
20      has me wondering is what are the drivers that have  
21      got you to clean up those six sites? That your  
22      workers are getting exposures higher than you want,  
23      or that you're seeing that in the plant life or the  
24      animals or it's leaching to the groundwater?  
25      What's making you even move the soil at all?

1       What's the driver?

2               MR. OLENICK: Do you have a copy of the  
3 proposed plan? Let me answer that for you. His  
4 question was, what are the drivers. What is  
5 forcing us to go clean these things up? Table 2 in  
6 your proposed plan summarizes those drivers. The  
7 individual contaminants of concern and what the  
8 pathway was that triggered the response action.

9               AUDIENCE MEMBER: I don't understand  
10 pathway.

11              MR. OLENICK: What I will explain is,  
12 that say, for instance, on that table, what it says  
13 is cesium-137, food ingestion. In other words, if  
14 crops were planted a hundred years in the future on  
15 those sites --

16              AUDIENCE MEMBER: But you're not going  
17 to plant crops.

18              MR. OLENICK: But it assumes that.

19              AUDIENCE MEMBER: Why would you do  
20 that? Are you trying to spend my money?

21              MR. OLENICK: If you walk away from the  
22 site, the EPA models assume that that land is  
23 available for land use.

24              AUDIENCE MEMBER: You know damn well  
25 you're not going to walk away from the site.

1       That's a given.

2               MR. OLENICK:   That's correct.   And then  
3       you'd have no risk.   The key to remember, though,  
4       is that we must model according to land use  
5       scenarios that make that land available to anyone  
6       or everyone, and so we have to use worst-case  
7       scenarios in all cases.

8               AUDIENCE MEMBER:   That's the driver?  
9       Where does that direction come from, EPA?

10              MR. OLENICK:   It is.   All those models  
11       we looked at --

12              AUDIENCE MEMBER:   It's a CERCLA  
13       requirement?

14              MR. OLENICK:   It is.   To evaluate all  
15       those pathways.

16              AUDIENCE MEMBER:   I thought you could  
17       make a choice.   I didn't think CERCLA drove you.

18              MR. OLENICK:   I'll let the regulatory  
19       agencies address that.   That's really what you're  
20       asking.

21              AUDIENCE MEMBER:   I didn't know you were  
22       planting crops out there.

23              MS. ENGLISH:   As far as the CERCLA  
24       process that we operate under, we have a set in  
25       process to evaluate risk and this process is

1 generally standardized throughout all sites across  
2 the country. You do have some flexibility in it,  
3 as far as how you tailor the scenarios. Typically  
4 on a Superfund site, a scenario may be 30 years, a  
5 future resident who is living at the site for 30  
6 years starting at present. On the INEEL, we did  
7 use land-use assumptions.

8 In general, there is a consensus among  
9 the agencies that it is reasonable to assume that  
10 the government will maintain controls over the  
11 INEEL for at least the next 100 years. That has  
12 been factored into our scenario. Therefore, those  
13 evaluation of scenarios do not start until 100  
14 years in the future, and then the residential  
15 scenario applies to 30 years beyond that.

16 At this time there is no reason for the  
17 agencies to extend beyond that time. There is just  
18 too much uncertainty out there. So the answer is  
19 correct. There is a set process that needs to be  
20 maintained, but we have taken land-use assumptions  
21 into consideration, and we have adjusted the  
22 pathways and scenarios that we're looking at to  
23 include that potential future land use.

24 AUDIENCE MEMBER: Let me understand  
25 this. Then are you saying that you clean those six

1 areas up and you cap this over in your other two  
2 areas, and after a hundred years, then you could go  
3 grow crops in those leaching areas or whatever you  
4 call them? Is that what you're saying? Because  
5 that's what I heard.

6 MR. HUTCHISON: What that's assuming is  
7 that in those six areas, you're right. We can  
8 go -- in 100 years, establish a residence and go  
9 farm there. The landfill covers are going to have  
10 institutional controls. They'll have deed  
11 restrictions, some sort of --

12 AUDIENCE MEMBER: So the EPA is telling  
13 me that it would be okay for me, in a hundred  
14 years, to build a home there within several hundred  
15 yards of that cap?

16 MR. HUTCHISON: That is right.

17 MR. ROSE: I want to reemphasize that  
18 this is a hypothetical scenario. The most likely  
19 use of INEEL for the next 100 years is government  
20 controlled activities, maybe limited industrial  
21 use, but we're required under CERCLA to look at  
22 potential future hypothetical residential  
23 scenarios, as well as the industrial, and then we  
24 have flexibility to pick among the various  
25 scenarios looked at and determine which one will

1 drive the cleanup. In this particular case, this  
2 site, it's the future residential scenario which  
3 drives the risk. In other words, drives it to a  
4 lower level. It is a slightly lower level than  
5 current industrial use. So the intent is to clean  
6 up for that lower standard.

7 So if, in 100 years from now, there is  
8 some residential use, there won't be any  
9 residential use in the capped areas for the  
10 preferred alternative, that will always be  
11 restricted. No one will build houses or grow crops  
12 there, but in the adjacent areas around it, if  
13 someone comes along and it is permitted to build  
14 residences there, they would be protected under  
15 this action.

16 AUDIENCE MEMBER: If you made the  
17 assumption that NRF would be a testing station for  
18 the rest of time -- I don't know what the rest of  
19 time is in EPA terms -- would you clean it up? Is  
20 there any risk associated with it? Is that a no?

21 MR. OLENICK: Let's assume that if it  
22 were a Naval Reactor Facility for 500 years and a  
23 controlled government access, we would look at the  
24 levels of contaminants there, which are primarily  
25 the radionuclides, cesium and strontium, we would

1 look at those concentrations, look at how they  
2 would decay over time. If after 500 years that  
3 stuff was below levels of concern, we might take a  
4 different action. It may go with just controls,  
5 control access to the site and no capping required  
6 if that were the case. But I think as you heard,  
7 there is no assurance that the government will be  
8 there after a hundred years from now.

9 AUDIENCE MEMBER: Other studies -- in  
10 other studies that you've done, the contamination  
11 levels for the level of contamination that you  
12 began to be interested in was in nanocuries. What  
13 is this PCI, is this picocuries?

14 MR. RICHARDSON: The question is a  
15 question of the terms of the measurement that we  
16 used. PCI is picocurie, is one trillionth of a  
17 curie. A nanocurie would be one 100 hundred  
18 millionth of a curie. So this is 1,000 times less  
19 than a nanocurie essentially. So they are very  
20 small numbers.

21 AUDIENCE MEMBER: The reason why this  
22 became a CERCLA site is because certain levels were  
23 exceeded as far as the groundwater and the basalt  
24 contamination and those other things?

25 MR. RICHARDSON: Actually, when you look

1 at the history of the Naval Reactors Facility, if  
2 the Naval Reactors Facility had been out there all  
3 by itself not surrounded by the rest of the INEEL,  
4 the levels of contamination there frankly would not  
5 have been of enough concern to place the Naval  
6 Reactors Facility on the national priorities list  
7 to make it a Superfund site. The contamination  
8 levels would not have been bad enough to get us  
9 listed, but since the INEEL has a number of  
10 facilities and it is considered one single federal  
11 site, we were included as part of the overall  
12 Superfund cleanup for the INEEL. Does that answer  
13 your question?

14 AUDIENCE MEMBER: You're saying that NRF  
15 really doesn't have that bad of a contamination  
16 problem as far as groundwater and soil?

17 MR. RICHARDSON: Yes. There are some  
18 problems. There are things we think we need to go  
19 clean up, but comparatively, particularly in  
20 relation to some of the other facilities at the  
21 INEEL, contamination levels, frankly, are pretty  
22 low. It doesn't mean that we don't think we need  
23 to go do some work. It's just on a relative scale  
24 they are low. Beatrice.

25 AUDIENCE MEMBER: I think I understood

1 Mark to say that you were going to be monitoring  
2 for 30 years?

3 MR. RICHARDSON: The question was -- to  
4 make sure that the assumption, preferred  
5 alternative that we would monitor -- the question  
6 is, with the assumption as far as monitoring, it is  
7 the institutional controls over the long term. The  
8 monitoring for the different alternatives,  
9 particularly the cost that assumes 30 years' cost  
10 for monitoring the institutional controls are, in  
11 fact, assumed to be in place for a hundred years.  
12 Those are for comparison purposes. Frankly, that  
13 doesn't mean that after 30 years we're just going  
14 to quite monitoring. But for the purposes of the  
15 study and to meet the scenarios and put them all on  
16 an even playing field, those are the assumptions we  
17 used for the model.

18 AUDIENCE MEMBER: In the government's  
19 agreement there was a 40 million earmark for  
20 (indiscernible).

21 MR. RICHARDSON: The question is, are  
22 the funds that were earmarked in the governor's  
23 settlement agreement towards -- the word you used  
24 was optional. I don't think it's quite the word,  
25 but it has the same intent. Are those funds

1 applied towards some of this work? In fact, some  
2 of those funds, in fact, may be applied to this.  
3 Most of those funds are applied towards other  
4 remedial -- I won't call it remedial action --  
5 other cleanup actions that are not necessarily  
6 CERCLA based. The things that, as a program  
7 meeting, our own standards we feel we need to go  
8 do. Discretionary, I think is the term in the  
9 settlement. Are there any other questions?

10 AUDIENCE MEMBER: You mentioned  
11 monitoring a few times. What kind of a monitoring  
12 program do you envision?

13 MR. RICHARDSON: The question is what  
14 sort of monitoring program do we envision. As Mark  
15 spoke earlier, we have -- remembering that this is  
16 the north groundwater on the INEEL flows across NRF  
17 essentially from the north to the south. We have  
18 an entire system of groundwater monitoring wells,  
19 six new ones that were placed about two years ago  
20 along with some U.S. Geologic Survey wells that  
21 monitor primarily on the down-gradient side, but we  
22 also have up-gradient wells that we can use for  
23 comparison. So we have wells all around the  
24 place. So we do quarterly groundwater monitoring.  
25 We also have in place and have had in place since

1 the 1960s additional environmental monitoring. We  
2 go out, we take soil samples. We take vegetation  
3 samples, particularly in places that we thought had  
4 the potential for contamination. So it's a  
5 comprehensive monitoring program with an emphasis,  
6 frankly, on the groundwater.

7 AUDIENCE MEMBER: After you see it in  
8 the groundwater, what would be the response?

9 MR. RICHARDSON: If, in fact, you saw  
10 contamination in the groundwater, at that point --  
11 that gets back to the five-year review that we  
12 discussed earlier, making sure that the actions we  
13 are taking remain protective. If, in fact, we saw  
14 a change in contamination levels in the  
15 groundwater, we get back with the EPA, we get back  
16 with the state, we make a determination on is there  
17 some anomaly. Do we think that, in fact, our  
18 remedy isn't as protective as we thought it was  
19 going to be, and how do we need to change that  
20 remedy to make sure that it is protective. So it  
21 would be a collaborative decision, again, between  
22 the three agencies. I'm sure that there would be  
23 public involvement in that process also, but  
24 there's a five-year review process to make sure  
25 everybody is, in fact, happy with the way the

1       system is performing.

2               MR. OLENICK:  If I could add to that,  
3       also the data is submitted to the state and EPA  
4       after each quarterly monitoring period.  So it's  
5       actually shared with the regulatory agencies and  
6       they continually look at that data as time goes on  
7       to ensure that those actions remain protective.  
8       That's how we do it now.  Based on the preferred  
9       alternative that isn't selected yet, we will either  
10      add or tweak that program, depending on what the  
11      selection is.

12              MR. RICHARDSON:  Are there any other  
13      questions?

14              AUDIENCE MEMBER:  Do you perform any  
15      monitoring in the vadose zone to give you an  
16      earlier indication of possible contaminants rather  
17      than waiting for it to get all the way to the  
18      groundwater?

19              MR. RICHARDSON:  The question is do we  
20      do any monitoring in the vadose zone, which is the  
21      unsaturated zone between the land surface and the  
22      aquifer which, at NRF, is about 370 feet below  
23      grade.

24              MR. OLENICK:  We did.  We monitored -- I  
25      forget.  I think we had 80-something perched water

1 wells. I forget how much we had sprinkled all over  
2 the facility. The areas we're talking about have  
3 no more perched water underneath them. That has  
4 long since dissipated and dried up, so the only  
5 water source that we've really got is the aquifer  
6 itself. Since there's no driving head, there's  
7 really no need to go off and keep looking for water  
8 underneath those when there is none present, but we  
9 have in the past.

10 MS. ENGLISH: I just wanted to emphasize  
11 that since this is not a selected remedy, we have  
12 not developed a monitoring program yet, so if the  
13 consolidation and capping approach, as it becomes  
14 the selected remedy, then the agencies will get  
15 together and determine a monitoring strategy of  
16 frequency, duration type of monitoring that best  
17 meets the needs to demonstrate continued  
18 protectiveness of the remedy. That could. Right  
19 now, it hasn't been including vadose zone  
20 monitoring, but it could. We have looked at the  
21 vadose zone for other remedies on the INEEL,  
22 including some landfills at NRF that were part of a  
23 previous remedial action. But to state just what  
24 exactly the monitoring will be at this time is a  
25 little premature, because we're just trying to

1       determine what the remedy will be.

2                   MR. RICHARDSON:  Are there any other  
3       questions?

4                   AUDIENCE MEMBER:  I was wondering,  
5       plants (indiscernible)?

6                   MR. RICHARDSON:  I think the question  
7       had to do with use of plants to remove  
8       contamination from the soil.  That's for -- that  
9       goes to the next presentation which is for the  
10      Argonne National Laboratory-West.  We at the Naval  
11      Reactors Facility don't have any current plans to  
12      start dry farming out there, or wet farming for  
13      that matter.

14                  AUDIENCE MEMBER:  You mentioned two  
15      possible options for the NRF facility in the  
16      future.  One, you said it might be through the  
17      purview of the government.  You also mentioned it  
18      might be converted to agricultural use.  Have  
19      you considered making it -- trying to restore  
20      the native vegetation that was here when  
21      Captain Rickover came through and putting buffalo  
22      that was there a hundred years ago and make it more  
23      of a nature preserve?

24                  MR. RICHARDSON:  The question goes to  
25      future plans or potential plans for land use at the

1 Naval Reactors Facility. As discussed earlier, our  
2 plans look at residential scenarios primarily. The  
3 question is, what about maybe turning it back to a  
4 more native state similar to a hundred years ago or  
5 so. From the standpoint of the assumptions that we  
6 had used in the analysis, no. We looked at the  
7 residential scenario. We looked at the worker  
8 scenario for the modeling. Now, does that  
9 necessarily preclude some of those -- returning it  
10 to a natural state? Not necessarily. Let me ask  
11 Bruce Olenick to speak to that also.

12 MR. OLENICK: Your question is, did we  
13 take a look at the impacts on native vegetation as  
14 well as plant and animal species -- or animal  
15 species, and you've got to keep in mind here -- and  
16 you'll hear Argonne a little bit later -- the  
17 primary difference between NRF and Argonne  
18 contamination problems is that NRF's contamination  
19 problems are basically 10 feet below ground,  
20 eliminating that pathway. That cover is to ensure  
21 that there is no integration of animal species to  
22 come in contact with that contamination.

23 Argonne, on the other hand, their  
24 concerns are more spread on the surface where they  
25 do have ecological risk. So, again, our drivers

1       were human health, of something, digging a house  
2       and building a foundation in that. Whereas from an  
3       animal perspective, there is no pathway for them to  
4       get at that. So we did consider that in a hundred  
5       years from now raising -- in those areas of these  
6       six sites, if we were to clean them up and cap, it  
7       would be acceptable to those animals.

8               AUDIENCE MEMBER: My question is more  
9       direct. Why don't we restore it and make it a  
10      wildlife preserve as opposed to something that  
11      should be considered when you do these. For  
12      instance, I don't know what kind of footprints the  
13      buffalo might make in your cap. If you had enough  
14      buffalo, you would have some kind of a dent in it.

15             MR. OLENICK: Remember the caps are  
16      going to be designed to prevent animal intrusion  
17      there. Again, that was a representative cap. If  
18      that is a selected alternative, the federal  
19      research that goes into the development of those  
20      caps are to have huge boulders. I think SL1 uses a  
21      similar capping scenario to keep animals off those  
22      areas. So that is considered, though.

23             MR. RICHARDSON: Beatrice, I think that  
24      you were next.

25             AUDIENCE MEMBER: My understanding is

1       that the land use assumption has been discussed and  
2       gone out in draft form and had public comment, and  
3       I think at some point the agencies just have to  
4       make some assumption, based on public comments and  
5       advice, on what the land use is going to be so that  
6       you can go ahead and do some planning based on  
7       that. But I think in the long term, there will be  
8       a continuing discussion that we should all take  
9       part in about what happens next.

10               MR. RICHARDSON: Part of the question of  
11       whether or not you return this to a natural  
12       environment has to do with the process when you  
13       actually tear down the buildings. At NRF, at  
14       least, some of the buildings are currently in use.  
15       Beatrice said there really is -- has been an  
16       ongoing dialogue and perhaps needs to perhaps come  
17       to some better focus on what the long-term land use  
18       planning really is for INEEL. But when the time  
19       comes to make the decision on what -- or any of the  
20       other facilities out there, is there a process  
21       under the National Environmental Policy Act that  
22       also goes through the same sort of evaluating  
23       process at public hearings and input, and it's at  
24       that point where that kind of decision gets made  
25       rather than this rather narrow one here. I would

1     like to say that at other places where the Naval  
2     Reactors program operates that we have shut down,  
3     our general intent is to allow it to be returned to  
4     any use including return to native species.

5             AUDIENCE MEMBER:   In your waste streams  
6     that have been percolated in your pits at S1W and  
7     so forth, have there been any steps to remedialize  
8     the types of waste and how they may affect water?  
9     In other words, the solubility of the waste.   I  
10    notice that cesium and strontium are both either  
11    alkaline or alkaline earth metals.   They absorb  
12    into water.   As metals they oxidize easily.   Have  
13    you taken any remedial steps as far as the chemical  
14    content of these waste streams?

15            MR. RICHARDSON:   The question that -- if  
16    you didn't hear it, to make sure I understand it,  
17    it was, have we taken any sort of steps in the  
18    contamination that is currently in the soil to  
19    either reduce the mobility of the contaminants that  
20    are already there?   That seemed to be the thrust of  
21    the question.

22            AUDIENCE MEMBER:   I'm concerned with  
23    seepage into water tables.   If the solubility is  
24    such that water dissolves it and it goes away,  
25    particularly into the aquifer, is there any

1 remediation steps that you've taken to keep it out  
2 of the air or water?

3 MR. RICHARDSON: I guess the -- if I can  
4 use the term -- and I'll probably be corrected if I  
5 use it incorrectly -- it sounds like, have we  
6 considered some sort of treatment of the material  
7 that's in the soil prior to initiating the remedial  
8 action that we're planning? The answer to that  
9 really is, no. One of the reasons for that,  
10 frankly, is when we've done the sampling primarily  
11 in the areas of the leaching pit, leaching beds,  
12 what we have found, by and large, is that the vast  
13 majority of that contamination is already bound  
14 fairly securely in that soil.

15 When we sample, we went from the surface  
16 all the way down to the basalt, which on the  
17 average is about 30 feet below ground level at the  
18 Naval Reactors Facility, and we would normally take  
19 samples in every two to four feet. We would pay  
20 particular attention at the level that those  
21 discharge pipes were at. What we found was the  
22 bulk of the contamination has stayed from about the  
23 discharged level to three or four feet below that  
24 because of the soil type that was in those pits,  
25 and, in fact, it does not appear that those

1 contaminants at this point, particularly leaching  
2 beds, are migrating down. So again, you have the  
3 balancing act of do you go off and try to do some  
4 sort of treatment to stabilize it but, in fact,  
5 destabilize it while you're trying to do the  
6 treatment when the evidence shows that right now  
7 it's pretty immobile. Again, those are the risk  
8 management decisions that are taken into account.

9 MR. OLENICK: I also wanted to mention  
10 that -- and you bring up a very good point. We did  
11 look at all that. The modeling we did -- also we  
12 made some pretty big assumptions. I'm assuming  
13 that cesium is again placed in a soluble form and  
14 made available to travel through the soil. That's  
15 a big assumption first. And then we also assumed  
16 maximum rainfall and flood conditions to assume  
17 that we had a driving head to force that down in  
18 our modeling, and so with all those conservative  
19 estimates throughout that modeling process, we did  
20 not model any detection in the groundwater. So we  
21 did assume that because the contamination levels  
22 are low and because of where it's found in the soil  
23 there, the answer to your question, yes, we did do  
24 that, but we didn't feel it was necessary.

25 AUDIENCE MEMBER: Related to that, did

1     you look at the daughter products, cesium decays to  
2     something -- are the daughter products -- have the  
3     same insolubility, or somewhere down the chain  
4     could it become soluble and have a daughter product  
5     that also might be somewhat of a risk driver?

6             MR. RICHARDSON:   The short answer is,  
7     yes.

8             AUDIENCE MEMBER:   That's a good enough  
9     answer.

10            MR. RICHARDSON:   Are there any other  
11     questions?

12            AUDIENCE MEMBER:   That is a pretty  
13     picture, that engineered cutout.   How far along is  
14     that?

15            MR. OLENICK:   That was a hypothetical  
16     cap.   We have a whole resource of information  
17     technology to go off and use if that's the selected  
18     alternative.   That was to give you an example of  
19     the types of things we're thinking about.   All that  
20     information will be assimilated and evaluated if  
21     that alternative is selected.   We either will  
22     enlarge the sizes and the thickness of the  
23     individual layers.   Permeability is considered.   So  
24     all that is evaluated in the RDRA, the remedial  
25     design, remedial action phase that begins next

1 fall.

2 AUDIENCE MEMBER: You don't have the  
3 contract yet?

4 MR. OLENICK: That's correct.

5 MR. RICHARDSON: We need to, in fact,  
6 select a remedy, then the next step which we  
7 anticipate performing next summer is getting into  
8 the actual hard engineering design of, if, in fact,  
9 we choose covers, now we get into the good, hard  
10 engineering of what design cover do we want to  
11 use. Are there any other questions?

12 MR. SIMPSON: Who does not have a copy  
13 of this proposed plan but would like one? If I can  
14 see a show of hands. One person. We'll get you a  
15 copy. We're at the portion of the meeting where  
16 you can comment for the record. As I mentioned  
17 earlier, we have a court reporter present who will  
18 be recording your comments verbatim. I should also  
19 mention that you can comment using the comment  
20 forms in the back of the proposed plan, or we can  
21 get a tape recorder and record you if don't want to  
22 make comment in front of everyone.

23 AUDIENCE MEMBER: The written comments  
24 are also part of the record?

25 MR. SIMPSON: Correct. I should mention

1       that when you do comment, please clearly speak your  
2       name and give your mailing address so that when the  
3       agencies respond to your comment in the  
4       Responsiveness Summary of the Record of Decision,  
5       we can send you that document. Can I get a show of  
6       hands who is interested in commenting for the  
7       record. I'm going to bring the microphone around  
8       to help out of the court reporter.

9  
10                               PUBLIC COMMENT

11  
12                   AUDIENCE MEMBER: I'm just submitting a  
13       written comment.

14                   AUDIENCE MEMBER: I'm concerned about  
15       the proposed engineering design. My name is Buck  
16       Sisson. I live in Idaho Falls. My home address is  
17       6047 West 17 South, 83402. I'm concerned about the  
18       proposed engineered burial over the top. It has a  
19       tendency -- it will maximize infiltration, probably  
20       collect snow and a lot of infiltration that is  
21       going on, really accelerating migration that should  
22       take place. I think that would be -- I'm worried  
23       about the engineered burial that is going to  
24       maximize infiltration and it will trap snow, and  
25       there won't be any plants growing, so it will

1 maximize the infiltration and the leaching of the  
2 soluble waste.

3 There are much better alternatives than  
4 that. DOE spent quite a bit of money on developing  
5 cap or barrier designs that minimize that leaching  
6 effect, and it should be seriously considered.  
7 Also the monitoring system should be in place in  
8 the vadose zone so you get an early warning if  
9 anything goes haywire. You'd have plenty of time  
10 to make remedies and fix it.

11 MR. SIMPSON: Thanks. Anyone else?

12 AUDIENCE MEMBER: My name is Joe  
13 Morted. My address is 496 South Pendlebury Lane,  
14 Blackfoot, Idaho. I would like to see a sharing of  
15 the technologies and the study data and the other  
16 ways that they have used to make decisions, and I'd  
17 like to see the modeling made available so that we  
18 can understand weather and understand groundwater  
19 phenomena and also deep water phenomena at the site  
20 and also in our areas. I've noticed in the  
21 previous studies that they've used models for  
22 weather forecasting that weren't based on our  
23 particular area. I would like to see a dynamic  
24 model of the Snake River Valley developed. I think  
25 it would help not only the site but agriculture and

1 all this. These are probably some of the spin-offs  
2 that could happen from this wonderful science that  
3 we're seeing, and I would like to see more of that  
4 happen.

5 MR. SIMPSON: Thank you. Any more  
6 comments? I would like to remind people that the  
7 comment period remains open on this project, and  
8 then also the next one that we're going to be  
9 discussing until February 10th. At this time I  
10 would like to take about a five-minute break and  
11 come back and we'll discuss the Argonne National  
12 Laboratory-West Comprehensive Investigation.

13 (Break.)

14 MR. SIMPSON: At this time I would like  
15 to introduce the agency counterparts for the  
16 Argonne National Laboratory-West Comprehensive  
17 Remedial Investigation/Feasibility Study.  
18 Representing the state of Idaho, Division of  
19 Environmental Quality is Daryl Koch. And once  
20 again, Keith Rose is representing the Environmental  
21 Protection Agency, and they are both going to make  
22 a few statements about this investigation.

23 MR. KOCH: Good evening. We seem to  
24 have lost our audience. I just shortly came on to  
25 this project from my predecessor at the DEQ, but he

1 did a very good job as well as the other agency  
2 representatives. I would like you to know this  
3 project is about one year ahead of schedule, one  
4 year ahead of milestone schedule. There's some  
5 minor upsets along the way, but that does happen  
6 with paperwork that we handle a lot of. So I want  
7 to applaud my counterparts for bringing it along so  
8 quickly.

9 In the WAG 8 demonstration earlier on  
10 NRF, Rick Nieslanik, when we opened up the  
11 presentation, talked about the similarities and  
12 differences you might see between the two  
13 projects. I just want to emphasize that a little,  
14 and sort of set a framework for you of the site as  
15 to why we came up with the preferred remedy. It's  
16 not been selected yet, but guess I'm trying to do a  
17 sales job here tonight on why we think it's the  
18 best alternative for remedial action.

19 Now, if you look at the overhead view of  
20 Argonne National Laboratory-West -- I'll just call  
21 it Argonne for tonight's purposes -- as well as  
22 with NRF WAG 8 before, both of these sites are in  
23 what we call an arid site. You wouldn't say that  
24 walking outside tonight, but this is obviously --  
25 this is an arid desert climate, eastern Idaho. So

1 ignore the snow. During the summer it gets very  
2 hot here, a lot of wind. Everything evaporates  
3 quite readily. I think we're under 10 inches per  
4 year of annual precipitation. That is considered a  
5 desert ecosystem. You've seen the kind of plants  
6 and animals we have out there, sagebrush. It  
7 doesn't need a lot of water. Grasses, certain  
8 kinds of grasses, et cetera.

9 So basically, as I said, I want to lead  
10 you into sort of the type of remediation we've  
11 selected, preferred remedy, and set the stage  
12 here. Obviously it looks very dry, doesn't it. As  
13 you see, though, there is water, sewage lagoons.  
14 There's an industrial waste pond. And feeding this  
15 particular industrial waste pond are several  
16 ditches, identified Ditch A, B and C, interceptor  
17 canal, et cetera, to our blowdown ditch, industrial  
18 waste lift station discharge ditch, and in -- for  
19 past practices, which is really what CERCLA looks  
20 at, looks at past practices when they're --  
21 basically, the kind of regulations we have today we  
22 look at potential releases from those sites and  
23 actual releases, and that's what you'll hear from  
24 the Argonne representatives after me talking about  
25 what they look for, what they found, what their

1 risks were, why we're doing a preferred remedy  
2 cleanup and the risk assessment process they went  
3 through.

4 I just want you to focus, if you can,  
5 though, on this overhead. What we have is a dry  
6 site, but we've added water. When you add water to  
7 the desert, things grow. In this particular case,  
8 you can't see it from the overhead, but in these  
9 ditches, et cetera, what Argonne has created by use  
10 of groundwater from 300 and some feet below the  
11 surface is a mini-ecosystem. As you drive down the  
12 highway when there is water in the ditches, you  
13 will see often cattails and reeds and other  
14 grasses. You'll see blackbirds, red wing  
15 blackbirds. You see all sorts of species.

16 Well, the same things happened down  
17 here. You add water and miraculously seeds get  
18 there. Birds bring seeds in and other animals and  
19 things grow. They just don't normally grow in the  
20 desert. Cattails don't grow out where sagebrush  
21 usually is. But in this case it does. So with  
22 these intermittent discharge streams -- and they  
23 are intermittent still. There is flow in these  
24 ditches. It's -- a typical little ditch would be  
25 maybe five or six feet across, a few inches deep of

1       water flowing through it.

2                       But along this ditch is an ecosystem.  
3       It's quite novel out there. I saw a beautiful  
4       yellow bird when I was out there a few months ago.  
5       I've never see that kind of yellow bird. I don't  
6       know what it was. Obviously it was attracted to  
7       this type of environment. There's bugs for it to  
8       eat. There's all sorts of goodies going on out  
9       there. So what this has created is a  
10       mini-ecosystem. So as you hear their presentations  
11       and risk assessment performed on these ditches for  
12       the contaminants of these previous releases, then  
13       you'll see we had discharge of heavy metals. We've  
14       had some discharge of radionuclides. Again,  
15       they'll talk about that more in detail.

16                      I just want you to focus on the system  
17       we have selected as preferred remedy which is  
18       phytoremediation, a long fancy word for plants  
19       doing what they normally do and uptaking metals,  
20       nutrients. They sometimes don't know the  
21       difference. That's a good aspect of what we're  
22       selecting because they take up the -- we'll call  
23       them the contaminants of concern here,  
24       radionuclides and other heavy metals that they  
25       don't normally take up because they're not normally

1 in a regular ditch by the side of the road. But  
2 again, due to these past releases, they are there  
3 now.

4 So this novel approach, which we, as the  
5 state, are really emphasizing, we are very  
6 aggressive on saying we would like you to consider  
7 this alternative is that the plants themselves that  
8 are in the ditches, we already know they are  
9 uptaking some of these metals. Like I say, they  
10 really can't help it to some degree. But Argonne  
11 wants to go to off, and they are doing the  
12 feasibility study now actually, back at Argonne  
13 East in Chicago, to look at other plants native and  
14 maybe non-native with low impact to the  
15 environment. That could be other types of plants.  
16 It could even be young sapling trees which will  
17 really suck up water, and you'll hear about those  
18 different kind of species.

19 So I just want you to concentrate, hear  
20 all the technical presentation. The state of Idaho  
21 is looking at kind of a simple thing here. These  
22 are high tech reactors. You will hear about the  
23 processes that went on, very fancy reactors and  
24 that we're looking for a solution that is Mother  
25 Nature's way of cleaning up the environment and

1       trying to protect the ecosystem ANL-West has itself  
2       created which will be there for probably several  
3       more decades because there will be some  
4       intermittent flow in these ditches. So I just want  
5       you to take a look at that and see if you agree  
6       with the selected remedy we have selected. Thank  
7       you.

8               MR. ROSE: Good evening again. I'm  
9       Keith Rose. I'm also EPA's remedial project  
10      manager for the Argonne Lab-West site as well as  
11      the NRF site. And the comments I made previously  
12      on the NRF site also apply to Argonne. EPA has  
13      reviewed and approved the Remedial Investigation  
14      and Feasibility Study for the Argonne Lab, and we  
15      have reviewed and concurred on the proposed plan  
16      including the preferred alternative which is  
17      phytoremediation which you're going to hear about  
18      tonight. Of course, this preferred alternative is  
19      based on seven of the nine criteria which I  
20      discussed earlier.

21             The two remaining criteria which are  
22      very important are state acceptance and community  
23      acceptance, which this meeting is part, and the  
24      public comment period and the proposed plan is part  
25      of gathering public comment on the preferred

1 alternative and proposed plan. I would like to  
2 say, though, that the preferred alternative which  
3 is part of remediation is an innovative  
4 technology. It has the potential for  
5 cost-effectively sequestering or taking up the  
6 contaminants of concern and removing them from the  
7 environment. So we're very interested in the  
8 outcome of this -- of this technology. As you'll  
9 hear later, there's been some bench scale tests  
10 we've conducted prior to the Record of Decision to  
11 see whether it, in fact, has the potential to  
12 work. I will leave that to Scott Lee to tell you  
13 more about that. Thank you.

14 MR. SIMPSON: At this time I would like  
15 to introduce Greg Bass. Greg is with the  
16 DOE-Chicago operations office which manages Argonne  
17 National Laboratory-West. He's going to talk about  
18 the facility background and a little bit about this  
19 investigation.

20 MR. BASS: Thanks for coming out  
21 tonight. As advertised, I am Greg Bass. I am the  
22 DOE Waste Area Group 9 manager and have been since  
23 1991 when the Federal Facility Agreement for the  
24 cleanup of the INEEL was signed. I am the third  
25 leg of the three agency approval process for this

1     Reactor, another research reactor. And the only  
2     reactor that is still operating of the five and  
3     fueled is a neutron radiography reactor in the  
4     basement of this Hot Fuel Examination Facility that  
5     we still use to look at fuel samples.

6             Over the years, Argonne has had a  
7     variety of missions with national and international  
8     sponsors. Mainly since 1958, Argonne has done  
9     research on developing reactors that can shut  
10    themselves down safely and reactors that can  
11    recycle their spent nuclear fuel all in the same  
12    facility, meaning that spent fuel will be taken  
13    out, reformulated, and the fuel and its long-lived  
14    actinides, we call them, such as plutonium, would  
15    be put back in the reactor and burnt up while  
16    generating heat.

17            Some of our modern missions since 1990:  
18    We have done WIPP waste characterization. WIPP  
19    means Waste Isolation Pilot Plant. It's a facility  
20    down in Carlsbad. There's a lot of waste on the  
21    INEEL that is destined for that facility, but it  
22    can't go until a certain amount of that waste is  
23    actually visually verified to be what it says it  
24    is. We do that at Argonne and are continuing to do  
25    that. Our core mission right now is spent fuel

1 proposed plan, and briefly I'm going to go over a  
2 little bit about the past mission of Argonne  
3 National Laboratory and where we think some of this  
4 contamination of our ditches and pond bottoms might  
5 have come from. Once I tell you what the problem  
6 is, I'll get Scott Lee up here who works for the  
7 University of Chicago at Argonne National  
8 Laboratory-West to go through the remedial  
9 investigation process with you and how we narrowed  
10 our 39 sites down to the 5 that I'll show you in  
11 just a minute.

12 Just real quick, this is not a group of  
13 UFOs. This is Argonne National Laboratory-West  
14 where I work and have worked long and hard.  
15 Briefly, some of the major facilities, the  
16 Transient Reactor Test Facility is out here. It  
17 was used for many years to test nuclear fuels under  
18 extreme conditions of heat. Experimental Breeder  
19 Reactor-II is a liquid metal reactor. It was shut  
20 down in 1994 and has been defueled. The Zero Power  
21 Physics Reactor is this white one that looks like a  
22 spaceship. It was used to mock up reactor cores  
23 for much larger reactors over the years and has  
24 been shut down since '92. There's a small reactor  
25 inside this complex called the Advance Fast Source

1       stabilization research and development.   Primarily  
2       that means we take spent nuclear fuel that has a  
3       constituent that is reactive in the environment  
4       such as sodium, and through an electrometallurgical  
5       process, we separate that spent nuclear fuel into  
6       waste forms that we think are disposable in a  
7       geologic repository.   It's very important research,  
8       and we are working very hard on it right now.

9               Just briefly -- this is the same slide  
10       Daryl was talking to.   Over the long history of  
11       Argonne National Laboratory-West we've looked at an  
12       awful lot of fuel samples and done a lot of  
13       radiochemistry.   That's the field of chemistry that  
14       studies radioisotopes.   A lot of those fuel samples  
15       had to be dissolved and a lot of the liquid from  
16       that dissolution process, as well as just washing  
17       laboratory equipment, was formerly, in the '60s  
18       discharged into a sewer system which terminated in  
19       a leach pit called the EBR-II leach pit.   EBR-II  
20       Leach Pit was simply a rock-bottomed septic tank,  
21       very simple method of disposing radionuclides and  
22       it's a method we don't do anymore.

23               The leach pit is about 15 by 40 feet.  
24       You could probably park a medium-sized Winnebago in  
25       it.   The EBR-II leach pit is no more.   In 1993,

1 knowing that the sludge in the bottom of the leach  
2 pit and the piping leading to the leach pit were  
3 contaminated, we went ahead and removed that  
4 facility. We took the sludge out of the bottom.  
5 We demolished the concrete lid and walls of the pit  
6 and we took the piping out of the ground in this  
7 area, and filled the entire area with clean soil.  
8 So the leach pit is no more.

9           However, during its operation, it had an  
10 overflow pipe that went to this interceptor canal.  
11 This canal was constructed along the western side  
12 of Argonne-West to divert natural storm water flows  
13 around the Argonne site into this industrial waste  
14 pond, which is sort of a low spot on the site. The  
15 radionuclides that were in the leach pit overflowed  
16 on one or two occasions into this interceptor canal  
17 and storm water came along and carried the  
18 contaminants throughout the length of the canal and  
19 deposited some more into the bottom sludges of the  
20 industrial waste pond here.

21           This mound is just dredged material that  
22 was taken out of the interceptor canal after it was  
23 discovered to be contaminated. The mound is also  
24 contaminated with cesium-137. The notable thing  
25 about the industrial waste pond, the mound and the

1       interceptor canal is those are the only sites that  
2       posed an unacceptable human health risk of all  
3       these sites you see at Argonne-West. We looked at  
4       a total of 39 sites, and out of these, only five  
5       sites posed either a risk to human health or a risk  
6       to the environment and some posed a risk to both.  
7       You can count more than five sites here. There's  
8       nine labeled. These nine -- those five sites were  
9       split in some cases to make our analysis of the  
10      fate and transport of their contaminants simpler.

11               But this is the list. This is all the  
12      facilities that we find unacceptable contamination  
13      in at the present time. By unacceptable, I mean  
14      higher than the national standard or higher than a  
15      standard that would allow us to release it to any  
16      use, human or animal or plant or otherwise, for the  
17      future. Briefly, these ditches you see in here,  
18      Ditch C, the main cooling tower blowdown ditch, and  
19      Ditch A and Ditch B are primarily contaminated with  
20      heavy metal constituents that were used as  
21      corrosion inhibitors and slimicides and algaecides  
22      in industrial water uses such as cooling towers.

23               We ceased using things like chromates in  
24      the cooling tower water in 1980. The industrial  
25      waste lift station discharge ditch has some

1       photographic type chemicals that were discharged to  
2       it in the past, and those constituents remain in  
3       the sediments at the bottom of the ditch. It's  
4       important to note that all the contamination I'm  
5       talking about is very shallow. It's typically  
6       between zero and three feet below the bottom of  
7       these ditches, and therefore it's rather easy to  
8       get at should you want to go after this  
9       contamination.

10               Without stealing his thunder, I'll let  
11       Scott go through the remedial investigation process  
12       now, how we whittled our 39 sites down to this  
13       group, and also he'll describe to you the  
14       alternatives for doing something about this  
15       contamination that we explored, and he will go in  
16       some detail on a rather unique preferred  
17       alternative which is the use of phytoremediation,  
18       which is actually using a farmed plant in these  
19       ditch bottoms to uptake the contaminants of  
20       concern.

21               So I want to tell you a little bit about  
22       Scott first. Scott works for the University of  
23       Chicago, and the University of Chicago operates  
24       Argonne National Laboratory-West for the Department  
25       of Energy. Scott has been involved with this

1 remedial investigation process for over three years  
2 since it began and has worked long and hard  
3 on it. He is the authority on the Remedial  
4 Investigation/Feasibility Study report as well as  
5 the proposed plan. With that, Scott, take it  
6 away.

7 MR. LEE: Thanks, Greg. As Greg  
8 mentioned, at the Argonne National Laboratory we  
9 have investigated 37 WAG 9 sites. To evaluate  
10 those and do a good job evaluating those, we have  
11 broken those 37 sites down into 43 distinct units.  
12 That means separating an industrial waste pond from  
13 a ditch. They have different exposure parameters,  
14 different driving forces, in this particular case,  
15 water. In addition to that, this is a  
16 Comprehensive Remedial Investigation/Feasibility  
17 Study, and we included two sites located close to  
18 the Argonne facility. These are in WAG 10 as Rick  
19 has mentioned earlier. They are a closer  
20 facility.

21 One of those is a wind-blown  
22 contamination investigation. The second is a  
23 stockpile soil that is actually the dredged  
24 material from the interceptor canal. That was  
25 moved a short distance down the road. So we

1 included those in our Comprehensive RI/FS. Once  
2 again, the Comprehensive RI/FS evaluates how the  
3 risks in one site are related to the risks in  
4 another site. We have animals that cross over and  
5 use multiple sites, and so by individually looking  
6 at the risk in one site, you're not grasping the  
7 whole picture.

8 To complete the Comprehensive Remedial  
9 Investigation/Feasibility Study we have collected  
10 over 9,400 contaminant specific samples, and this  
11 is a summary of those results. As you can see on  
12 the left side of this chart we have started off  
13 with the investigations of the Track 1 and  
14 Track 2. Greg mentioned we have gone into and  
15 conducted a removal action at the EBR-II leach pit  
16 and all the other Track 1s and Track 2s were  
17 determined to be no further action. We again took  
18 all those sites to make sure we haven't missed any  
19 contaminants, to make sure we have assessed all the  
20 exposure parameters and pathways and incorporated  
21 those into our Comprehensive Remedial  
22 Investigation/Feasibility Study.

23 We have completed that and we have  
24 selected a preferred alternative, and we're now at  
25 this phase right here prior to going into the

1 Record of Decision where we're soliciting your  
2 input to make sure prior to the selection of the  
3 selected alternative. After that we will go into  
4 the remedial design, remedial action, continued  
5 monitoring and some sites will drop off as no  
6 further action.

7 This is just an overview of the exposure  
8 pathways at the Argonne National Lab which are  
9 similar to those evaluated by the Naval Reactors  
10 Facility. We have an occupational scenario. We  
11 have a current occupational scenario for a worker  
12 on site right now, working there for 25 years. We  
13 have a future occupational scenario that we  
14 evaluated, which is an individual starting 30 years  
15 from now and working for the next 25 years. We  
16 have assessed a residential scenario, which is an  
17 individual living at the site a hundred years from  
18 now and will continue living there for 30 years.  
19 And those are the pathways we evaluated:  
20 ingestion, inhalation, direct radiation exposure  
21 and dermal contact.

22 In addition to those, we have included  
23 groundwater ingestion, ingestion of homegrown  
24 produce and inhalation of inorganics in our case,  
25 for a future residential scenario. Those are not

1        assessed for the occupational since the current  
2        occupational and the future occupational do not  
3        drink as much water. We do not shower out there as  
4        often as a future resident would.

5                And based on this whole risk assessment  
6        process, we found that we only had one  
7        contaminant. That is cesium-137 that poses an  
8        unacceptable risk for the human health scenarios.  
9        I'll show you where those are. For the present day  
10       this is the occupational scenario. We have the  
11       three sites Greg pointed out, the industrial waste  
12       pond, the interceptor canal and the interceptor  
13       canal mound that pose unacceptable risks currently  
14       today. This is one in 10,000 risk level and you  
15       see were greater than that for all three of these  
16       sites. We have 37 sites that have risks below the  
17       threshold of one in 10,000 for human health, and  
18       we've eliminated those.

19               The contaminant, again, is cesium-137, a  
20       relatively short-lived radionuclide with a  
21       half-life of 30 years, and we have the actual  
22       radionuclide concentrations listed below. We have  
23       29.2 picocuries per gram, 18 picocuries per gram  
24       and 30.53 picocuries per gram, and remember every  
25       30 years these decrease by one-half. The actual

1 threshold criteria, this threshold line for the  
2 cesium-137 current occupational scenario is -- I  
3 want to say 16.7 picocuries per gram, so we do not  
4 have a very large delta right there as you can  
5 see.

6 I'll go on. We decayed those just to  
7 give you an idea of what those concentrations would  
8 be in the future. A hundred years from now the  
9 cesium-137 in the industrial waste pond would be  
10 2.83 picocuries per gram; interceptor canal, 1.75;  
11 and the interceptor canal mound, basically,  
12 3 picocuries per gram. You can see the interceptor  
13 canal itself. The risk is now below the one in  
14 10,000 through natural decay without doing  
15 anything. This one in 10,000 risk line is set at  
16 that time to be 2.2 picocuries per gram so these  
17 two remaining sites a hundred years from now are  
18 just slightly over for the cesium-137.

19 And again, just in summary you can see  
20 these three sites were all related to the same  
21 inadvertent release that flowed to the Interceptor  
22 Canal and to the industrial waste pond, and, again,  
23 this mound area is the stockpile of the dredge  
24 materials. We've also assessed the risk to the  
25 ecological receptors. This includes flora and

1 fauna, and we have determined, based on an  
2 individual animal receptor, not a population of  
3 animals, but on an individual basis, we have 12  
4 inorganics that pose potential risks to these  
5 individual animals.

6 This is a chart showing the hazard  
7 quotients and where each of these individual sites  
8 are as compared to what we're using for cleanup of  
9 a hazard quotient of 10. You can see we have  
10 hundreds and up to 10,000. Now, I have to put a  
11 caveat on here. A risk of 10 versus a risk of 100  
12 for a hazard quotient doesn't mean it's 10 times  
13 more hazardous to the ecological receptors.  
14 Remember back to Rick's diagram on hazard  
15 quotients. We have a -- it's a nonlinear function,  
16 and we have the observable effect, and we use in  
17 risk assessment a concentration lower than that,  
18 and so these -- we do not have what would appear to  
19 be a major problem on these ecological receptors.

20 Again, we have the sites shown on the  
21 map. Ditch A, Ditch B, Ditch C. We have two of  
22 the three sites with the human health risk have  
23 potential for eco risk which makes sense  
24 intuitively. We have the sewage lagoons, the  
25 industrial waste lift station discharge ditch and

1 the main cooling tower blowdown ditch. As Greg  
2 mentioned before -- or he didn't mention, the  
3 sewage lagoons we are currently using, and will  
4 continue to use these sewage lagoons for the useful  
5 life of the Argonne Facility, even though they  
6 appear to pose potential risks to the ecological  
7 receptors.

8 The reason for that is the exposure  
9 pathway for the unacceptable ecological receptor is  
10 a small burrowing mammal. This is a mouse  
11 burrowing in there, and as long as we have the  
12 water there, which typically is eight feet of  
13 water, there is no exposure pathway. And the same  
14 is said for the industrial waste pond, which  
15 currently has water and will have water until the  
16 year 2001. Once that site dries up, then we would  
17 start our remedial action on that to eliminate the  
18 exposure pathway to a small burrowing mammal.

19 As Daryl mentioned, the depth to  
20 groundwater is 365 feet. In our case at Argonne, I  
21 think he had the numbers mixed up. It's 635 feet  
22 to groundwater. Greg Bass mentioned that our  
23 contaminants are found within the top three feet of  
24 soil. Almost exclusively, contaminants are in the  
25 top foot of soil. We have very few contaminants

1 deeper than one foot and only a few of those extend  
2 past two feet on a very limited basis.

3 Basically, I've just gone through what  
4 our risks are, what these contaminants are and  
5 where those sites are located, and now I'm going to  
6 basically establish what we have gone through, how  
7 we're going to protect the human health and  
8 environment. We have established for human health,  
9 to use the NCP guidance of one in 10,000 as  
10 our criteria of cleanup and for the ecological  
11 receptors on a population basis, we're using a  
12 hazard quotient of 10 for our cleanup standards.  
13 We have evaluated 28 different alternatives for  
14 cleaning up these areas. We screened that list  
15 based on costs, implementability and a couple of  
16 other factors to a list of five alternatives which  
17 could be applicable at the Argonne National Lab  
18 Facility.

19 The first one is no action. The second  
20 is limited action. The third is containment in  
21 institutional controls on site at the Argonne  
22 Facility. The fourth is excavation and disposal,  
23 removal of those contaminants and sending them to  
24 either an on-site or off-site disposal, capping.  
25 The fifth is phytoremediation which involves

1     utilizing plants to extract these contaminants.  
2     Shown on the right side of this chart are the nine  
3     evaluation criteria. The first is protection of  
4     human health and the environment, and the second is  
5     complying with applicable laws. Those are the  
6     threshold criteria.

7             For any of these alternatives to be  
8     implemented, we have to at least be protective of  
9     these first two threshold criteria. If we do not  
10    protect human health and the environment or do not  
11    comply with all applicable laws, those are screened  
12    off. Based on those two criteria, no action,  
13    continue to do no action, does not meet the  
14    criteria, so we eliminated no action. We've  
15    eliminated limited action which involves just  
16    putting a fence around and watching, and we've  
17    eliminated one alternative. It's Alternative 3b,  
18    if I remember correctly, which is a native soil  
19    cover because the animals could potentially get  
20    through there.

21            The middle five criteria are what are  
22    called the balancing criteria. This is where we  
23    evaluate the retained alternatives with against  
24    each other based on those criteria. I will go in  
25    and show you the table and how we ranked each those

1 all alternatives against either other. And these  
2 last two criteria, we're here tonight to get your  
3 input on, making the decision for these last two  
4 evaluation criteria.

5 Once again, Alternative 3 is capping the  
6 contaminants in place. Limiting the migration of  
7 contaminants from the site. Isolating the  
8 contaminants and instituting institutional  
9 controls, fencing, deed restrictions to limit the  
10 potential exposure to a receptor. In addition,  
11 that would involve using air, ground and soil  
12 monitoring to make sure none of these contaminants  
13 are migrating from the facility or the containment  
14 facility.

15 Alternative 4 that we evaluated, we  
16 evaluated an Alternative 4a which looked at using a  
17 currently existing INEEL facility otherwise known  
18 as RWMC or potentially an INEEL soils repository  
19 which is yet to be built, and you will hear about  
20 that in the next couple months. It would involve  
21 removing the contaminants from the Argonne site,  
22 hauling them down to this on the INEEL location,  
23 and they would be placed in a cap at that  
24 location. The off-site would involve the same  
25 process for moving those contaminated soils to a

1 railhead and then transporting them to a private  
2 facility, most likely in Utah.

3 Alternative 5 is phytoremediation which  
4 is using plants to extract these contaminants from  
5 the soil using their natural ability. These  
6 plants have been around for millions of years, and  
7 they've adapted to various conditions and  
8 contaminant levels around the United States. It's  
9 natural for a plant to extract what it needs. The  
10 phytoremediation takes this one step further and  
11 selects the plant to put in there to remove your  
12 specific contaminant. The plant matter would be  
13 harvested, dried, baled and then sent off site to  
14 an incinerator. Comparing this with the other  
15 alternatives, obviously, if you're not moving the  
16 soil, you're removing plants. You've reduced the  
17 volume of material that you're moving to less than  
18 1 percent.

19 Then after the plant matter is at an  
20 incinerator, once that is burned, your volume of  
21 material is reduced considerably from that level.  
22 We're currently scheduled to use an INEEL  
23 incinerator for the disposal of our plant matter.  
24 As I said before, this is a chart comparing the  
25 alternatives that were retained against each

1 other. We have Alternative 3 which is containment  
2 on site. Alternative 4a, which is containment on  
3 the INEEL. Alternative 4b, which is containment  
4 off the INEEL. And we have Alternative 5 up here.  
5 These are ranked by the evaluation criteria against  
6 each other.

7 As can you see, we had to comply with  
8 all applicable laws, and we had to be protective of  
9 human health, so all of the criteria are ranked  
10 best or good for the first two, long-term  
11 effectiveness and permanence. Phytoremediation is  
12 a little better than the Alternative 4a because it  
13 involves permanence. Once you remove the  
14 contaminants, you don't have to worry about them  
15 being at another location. Short-term  
16 effectiveness, they are ranked about the same.  
17 Reduction of toxicity, mobility and volume through  
18 treatment, phytoremediation is the only alternative  
19 that we've retained for evaluation that is a  
20 treatment process. And so it's obviously ranked  
21 the best.

22 Implementability, these are readily  
23 implemented using construction equipment to build a  
24 containment. We have phytoremediation as being  
25 ranked as good because of the unknowns that exist.

1 A bench scale test to determine how many years we  
2 will have to do a field season to clean up these  
3 soils and how many different types of plants  
4 we will need to be conducted. So it's not as  
5 readily implementable. The costs are shown in the  
6 bottom. The costs for phyto are 2.8 million which  
7 would give the nod in this occasion. The next  
8 closest is on-site containment at an INEEL soils  
9 repository or RWMC and that's 5.9 million.

10 In summary, the Argonne National Lab  
11 has completed its Comprehensive Remedial  
12 Investigation/Feasibility Study. We had 37 sites  
13 specifically at WAG 9 and we've included two sites  
14 from WAG 10 in the proximity of WAG 9, and we've  
15 determined that 34 of those sites or areas require  
16 no additional action. We have identified nine  
17 areas with unacceptable risk, three areas for  
18 unacceptable human health risk based on the  
19 cesium-137, and we have identified eight areas with  
20 unacceptable ecological risks.

21 We have identified remedial alternatives  
22 and screened those alternatives and evaluated those  
23 alternatives and have determined along with DOE and  
24 the state EPA that Alternative 5 should be selected  
25 as the preferred alternative which involves the

1 using of phytoremediation to extract these  
2 contaminants. Based on that, we have already  
3 started a bench scale testing back in the  
4 University of Chicago on our soils that we removed  
5 from the ANL-West Facility to determine which  
6 plants we should use if this is the selected  
7 alternative and what are the uptake or how much of  
8 the contaminants are removed from these soils.

9 I would just like to add one other  
10 thing. If the cesium were left in place, it would  
11 take 130 years to decay to the one in 10,000 risk  
12 level. So that incremental portion of the cesium  
13 that we have to remove from our soils is very small  
14 at this particular site, and phytoremediation has  
15 been used in the past, and we think it will work  
16 out very well for the Argonne Facility.

17 We're here tonight to get public  
18 perception of using phyto. We're here to answer  
19 your questions, and we would like to hear your  
20 comments on this preferred alternative and the  
21 other alternatives that we evaluated. The comment  
22 period started January 12th and runs through  
23 February 10th. We are scheduled to have our Record  
24 of Decision this summer which includes the  
25 Responsiveness Summary which are our answers to

1 your questions tonight. And we're currently  
2 scheduled to begin implementing phytoremediation,  
3 if it is the selected alternative, this summer.

4 And with that, I would like to ask that  
5 Greg come up here, and if you have any questions  
6 concerning anything that we've presented tonight,  
7 to answer those.

8 AUDIENCE MEMBER: I have a couple of  
9 questions on the slide that you have on comparing  
10 the alternatives one to the other. I think three  
11 back or two. There you go. I'm curious to know  
12 why 3a, 4a and 4b only got a good on compliance as  
13 applicable on your ARARs? I do have a second  
14 question which I'll ask as well. Could you give us  
15 some idea on what has been done with  
16 phytoremediation, particularly any specific studies  
17 you can refer to and the details of those studies  
18 and what is known and what isn't known?

19 MR. LEE: The first question is  
20 compliance with ARARs. How come alternatives 3a,  
21 4a and 4b are ranked as being good and phyto is  
22 ranked as being -- as the best. This is a consumer  
23 report type diagram. You have to remember that to  
24 retain these alternatives, they all have to be able  
25 to meet the laws. Phytoremediation actually goes

1 through a treatment process to eliminate the  
2 potential risks of any ARARs. Once the  
3 contaminants are removed from the soil, the ability  
4 to treat the soil, we will not have the chance of  
5 having an unacceptable soil concentration for any  
6 of the ARARs. Does that make sense?

7 AUDIENCE MEMBER: Yes.

8 MR. LEE: These soils are going to be  
9 put in a containment system and will remain there  
10 and the laws are always changing, but once the  
11 phytoremediation is actually a treatment process  
12 and we do not have to worry once we meet the  
13 remedial action objectives of having a potential  
14 risk.

15 MR. KOCH: And if you look at this  
16 chart, it's like looking in a Consumers Report  
17 magazine which is basically what it is. You get a  
18 group of people in the three agencies, and if we  
19 discuss this probably another hour, we would  
20 probably change some of these things. It's very  
21 subjective other than probably the first two  
22 criteria. Beyond that it is really a discussion  
23 phase where we say, yeah, or, no, and say let's  
24 give it a half moon, let's give it a zero, let's  
25 give it a full moon. It is really a subjective

1 process, but the good thing is we have three  
2 agencies bouncing these ideas off each other, and  
3 it's not that we pushed everyone to be on the right  
4 as the full moon to get the phytoremediation, but  
5 essentially it just did come out this way, low  
6 costs, and so it is subjective to some extent. You  
7 have to understand that.

8 AUDIENCE MEMBER: I do, but my  
9 understanding of the second is that it needs to  
10 comply with all applicable laws and appropriate  
11 laws that are out there. And so if you were to put  
12 it in a containment, for example in a landfill, you  
13 would build that landfill to meet all applicable  
14 requirements for that type of landfill, and so --  
15 and you said that's got -- none of these will  
16 violate any law, but your point is that the  
17 phytoremediation will actually remove all the  
18 contaminants, hopefully, and in that sense, I think  
19 that is more protective of the human health and the  
20 environment, but I'm not going to quibble about  
21 whether the half moon or full moon. I just wanted  
22 to find out why you thought it didn't quite meet  
23 the requirements. It sounds like you think it did.

24 MR. LEE: To be retained, they have to  
25 meet requirements. We could have something ranked

1 the worst, the whole empty circle, and it could  
2 still be retained. It's relative to each other,  
3 but they have to meet the minimum. Those are the  
4 threshold criteria for being retained. If you  
5 remember, we screened off a couple alternatives  
6 because they didn't meet that.

7 MR. BASS: All of our alternatives  
8 comply with all laws and all regulations. It's  
9 just that the treatment for these contaminants  
10 eliminates any risk of contamination escaping from  
11 your landfills years and years in the future. Our  
12 potential of becoming noncompliant with some  
13 regulation is greatly reduced with the treatment of  
14 the contaminants through phytoremediation, whereas  
15 with the landfill options -- that's what I call  
16 them -- there is always that potential that  
17 something may go wrong at the landfill. That's the  
18 only reason it got a whole circle and the rest of  
19 them got a half.

20 AUDIENCE MEMBER: My point is that would  
21 make protection of human health and the environment  
22 with 4a and 4b half moon. That would make  
23 compliance that they were also. But I'm not here  
24 to quibble.

25 MR. BASS: Who else had a question?

1       Okay. You said where in the world are they using  
2       phytoremediation to extract contaminants from  
3       soil. At a DOE facility at Ashtabula, Ohio. DOE  
4       is removing uranium from soil in Ashtabula, Ohio,  
5       for one thing. DOE is also -- or at least  
6       phytoremediation is being used right now in the  
7       Ukraine near the Chernobyl accident site for  
8       removal of cesium also. Argonne National  
9       Laboratory, particularly the Illinois facility, has  
10      done a lot of research on cesium extraction from  
11      cows' milk, water and other environmental media.

12                Army installations are using  
13      phytoremediation, using plants to extract chemicals  
14      used in the manufacture of explosives, and I will  
15      give you a free copy of really good literature on  
16      phytoremediation after the meeting. Who else had a  
17      question? Marty.

18                AUDIENCE MEMBER: The plants that you  
19      have under consideration, are they native plants or  
20      are they non-native plants? If they are non-native  
21      plants, what precaution do you have to make sure  
22      that the non-native plants don't start taking over  
23      our desert environment?

24                MR. BASS: That's a good question,  
25      Marty. We had the same concern. Presently in our

1 greenhouse study back at Chicago, they are testing  
2 all kinds of different plants on our actual soil  
3 that we sent them from our ditches and pond bottoms  
4 using a variety of plants. We, of course, favor  
5 native plants, mainly because they need to be tough  
6 enough to take it out at the INEEL. Venus fly  
7 traps aren't going to cut it in eastern Idaho or  
8 Hawaiian pitcher plants or whatever those things  
9 are with the big flowers.

10 So I am prejudiced towards using native  
11 species. I advocate heavily using native species,  
12 and, in fact, willows and the poplar family,  
13 including aspen, are very promising plants for  
14 extracting out particular contaminants. I'd much  
15 rather see our ditches and pond bottoms covered  
16 with willows and aspen than Venus fly traps.

17 AUDIENCE MEMBER: I presume that when  
18 these plants that you harvested go to incineration,  
19 that the contaminants that you want to extract from  
20 the environment stay in the ash. What happens to  
21 the ash?

22 MR. BASS: That would be solidified  
23 according to the waste acceptance criteria for  
24 whatever radioactive waste landfill we would use.  
25 I want to go back up real briefly. I dodged part

1 of my question. If we were to use non-native  
2 species, even a non-native variety of a native  
3 species, they would be cut and harvested before  
4 they could go to seed and reproduce. We were very  
5 concerned about that. We know that a lot of our  
6 stakeholders including the Shoshone and Bannock  
7 tribes are concerned about introducing non-native  
8 species. Are there any other questions?

9 AUDIENCE MEMBER: What of the  
10 contaminants will remain in the ash and what  
11 volume? Which, on your list, is cesium, arsenic  
12 and that.

13 MR. BASS: The cesium will remain in the  
14 ash or it will be trapped in a HEPA filtration  
15 system at the incinerator plant.

16 MR. LEE: To answer that question, some  
17 of the literature that Greg can hand out later  
18 tonight describing inorganics and phytoremediation,  
19 they are actually looking at some of the  
20 concentration of inorganics in the ash after  
21 incineration are so high they could actually  
22 recycle that material. That's not the case for the  
23 Argonne facility, but all of the inorganics would  
24 be in the sludge and in the ash. The ash is tested  
25 and then solidified and sent off to the appropriate

1 facility.

2 AUDIENCE MEMBER: So this would be mixed  
3 waste?

4 MR. LEE: Potentially mixed waste. It  
5 depends upon the results. If you remember, we have  
6 distinct units for human health and distinct units  
7 for eco. We could send the RAD contaminated plant  
8 matter to an incinerator, typically the one at  
9 WERF, and we could send the inorganic sites off to  
10 a different incinerator where they do not have to  
11 have a license to incinerate RAD material.

12 AUDIENCE MEMBER: But some of the  
13 material will have -- I thought you said that there  
14 were sites that posed both human health and  
15 ecological.

16 MR. LEE: We have two sites that pose  
17 both. That is correct. But you have to remember  
18 again, once this is sent to the incinerator, the  
19 incinerator has acceptance criteria and they have  
20 to determine by sampling where they can dispose of  
21 that incinerated ash.

22 AUDIENCE MEMBER: Do commercial disposal  
23 facilities have concentration limits? I mean, if  
24 it is as you say, the inorganics are so  
25 consolidated that they can be recycled? Does a

1 hazardous waste landfill -- automatically, can we  
2 assume that any facility could take it or would it  
3 be that particular facility? I don't think that  
4 I'm expressing this very well. How concentrated  
5 are the hazards in this waste going to be and is  
6 that concentration of hazard going to determine  
7 where it's disposed of rather than the  
8 constituents?

9 MR. BASS: That's exactly right. Our  
10 goal really is to get this ash -- to get the  
11 contaminants in this ash at a high concentration  
12 level. We don't want a bulk of waste to dispose  
13 of. That's the beauty of this whole thing is  
14 volume reduction. So the ash would be carefully  
15 analyzed before going to and a hazardous waste  
16 disposal facility which has a permit and the permit  
17 tells them the waste acceptance criteria and the  
18 analytical method that must be used before they  
19 would accept this ash.

20 So, yes, it would be heavily  
21 contaminated with heavy metals. The ash would be,  
22 but it would be disposed of at a hazardous waste  
23 facility which is permitted for those levels of  
24 heavy metals. More questions?

25 AUDIENCE MEMBER: You know, when you

1       move waste from one medium to another, there's  
2       spills and problems and stuff going around. With  
3       the exception of the potential for mixed waste, how  
4       about taking just cement and allowing cesium -- and  
5       covering, like, the ditches or something with  
6       cement and allowing the cesium to decay and  
7       eventually go away.

8               MR. BASS: It would take 130 years for  
9       the cesium to naturally go through its radioactive  
10      decay to a level where it doesn't pose any human  
11      health risk. Scott literally looked at dozens of  
12      alternatives to taking care of these sites. Was  
13      concreting one of them?

14             MR. LEE: Placing concrete on top of the  
15      ditches and assuming the concrete would last for  
16      130 years is probably correct. But you haven't  
17      treated it, and the inorganics are always going to  
18      be there. You have cesium on one side and  
19      inorganics on the other. You eliminated the  
20      exposure pathway of the cesium to a receptor, but  
21      you haven't taken care of the inorganics. And  
22      you've made the assumption that they're going to be  
23      there or watching over 130 years. In the Argonne  
24      facility, we are currently targeted 35 years. We  
25      are kind of, quote, unquote, in the shutdown mode.

1       So we cannot guarantee that the concrete will still  
2       be there, so we feel it's better to treat it and  
3       meet the regs than to put a concrete cover on it.  
4       Does that make sense?

5               AUDIENCE MEMBER:   Yes.

6               MR. LEE:   Beatrice.

7               AUDIENCE MEMBER:   Let me return to where  
8       we're going a take this ash.  At the concentrations  
9       of the contaminants you assume will be in the ash,  
10      how many facilities in the county can take that?

11              MR. KOCH:   Regardless of the  
12      concentration any facility that has a application  
13      permit can let's say this was RCRA waste.  They did  
14      T-clip extraction from the RCRA waste.  Before it's  
15      buried in that landfill, it would have to undergo a  
16      land ban treatment.  It depends on what the metals  
17      are.  I don't know off-hand, but they would have to  
18      meet that criteria before it could be buried in  
19      that facility.  As you know the metals don't ever  
20      go away.  They don't decay.  So it's still always  
21      going to be there.  It will be in a very  
22      concentrated parts per million quantity in this  
23      mass of incinerator residue, ash as we call it.

24              So we still have to meet some criteria  
25      for whatever RCRA authorized landfill it would go

1 to. If it wasn't RCRA, it could go someplace with  
2 less stringent standards, so we don't know what the  
3 concentration will be, but just for instance we've  
4 seen concentration of several tens of thousands  
5 parts per million of some of these metals on some  
6 of these studies. So these plants do  
7 hyperaccumulate these metals. So we don't know the  
8 answer to that yet.

9 AUDIENCE MEMBER: I think the concern  
10 may be, though, how difficult do you anticipate it  
11 would be to find a facility that would accept the  
12 ash.

13 MR. KOCH: I don't think it's a concern  
14 at this point at all because I know there are  
15 facilities that will treat your waste so they can  
16 take your waste. It depends on how much it will  
17 cost. We don't have any studies on the  
18 leachability of that ash and that's what would have  
19 to be done. It takes quite a high concentration to  
20 reach of a T-clip standard to say it's a RCRA  
21 waste, but we don't have that yet.

22 AUDIENCE MEMBER: So it may have to be  
23 treated further before it would be --

24 MR. KOCH: That depends on the  
25 contaminant and the concentration. Yes, I don't

1 think we could say that we might not have to. It  
2 just depends. Is that good enough?

3 MR. LEE: If I'm interpreting correctly  
4 what you're saying, Beatrice, that is a normal  
5 process for the incinerator and these wastes will  
6 be acceptable. The inorganics are readily  
7 acceptable. We can solidify those and send those  
8 to a landfill. The radionuclides, if we end up  
9 with a mixed waste, they are currently doing that  
10 with much, much higher contaminants than we're  
11 dealing with here for phytoremediation on the  
12 INEEL. Does that answer it?

13 AUDIENCE MEMBER: What's your timeline  
14 for treatment? You say you start -- when did you  
15 say?

16 MR. LEE: I can show you after we have  
17 run through three scenarios assuming 3 percent  
18 uptake, 4 percent uptake and 5 percent. If we  
19 assume 5 percent uptake per year for the  
20 cesium-137, at 5 percent, it takes four years to  
21 clean it up with phyto. If we assume 3 percent,  
22 we're talking about six years of growing plants at  
23 the INEEL in these ditches. I can show you those.

24 AUDIENCE MEMBER: And you're planning to  
25 start in '99? I can't remember.

1 MR. LEE: '98. We have a greenhouse  
2 study currently being conducted at the University  
3 of Chicago on our soil, and we are also sending  
4 them our water to simulate as closely as possible  
5 the conditions at the site.

6 AUDIENCE MEMBER: In your risk  
7 assessment, have you taken into consideration the  
8 possibility of fire that could go through any plant  
9 material that's growing on the site and release  
10 contaminants into the environment?

11 MR. BASS: I don't know what would make  
12 you worry about a fire at Argonne-West because  
13 we've had two in the last three years. That is a  
14 good consideration. In the type of plants that we  
15 select again, we're favoring the willow and poplar  
16 family and others that store contaminants primarily  
17 in their root system. The reason that we're  
18 favoring those types is we don't necessarily want  
19 deer and large, good-looking herbivores nibbling on  
20 leaves and stems of these plants that have a high  
21 concentration of the contaminants that we're trying  
22 remove here. So if a fire were to whip through, it  
23 would burn the leaves and stems in these ditch  
24 bottoms and leave the roots alone.

25 MR. LEE: I would just like to add one

1     thing. As Greg talked about these plants, willows,  
2     poplars, we're not going to create an oasis.  
3     They're going to be planted as a crop. They're  
4     going to be planted and grown really closely  
5     together. We're not talking 15-foot trees here.  
6     And they will be harvested similarly to a potato  
7     digger where you're going in and scooping up the  
8     roots along with the plant material, so we envision  
9     that the tree will only be about three or four and  
10    five feet tall and harvesting after one year. So  
11    we're not creating habitat for an owl or something  
12    like that.

13               AUDIENCE MEMBER: During harvesting,  
14    what's going to be done about dust control?

15               MR. LEE: We can use suppression  
16    methods. We typically use those during  
17    construction, and I'm assuming we would have to,  
18    again, use those for control. Remember, typically  
19    at most we're talking 5 percent uptake. You're  
20    dealing with much, much higher concentration than  
21    radionuclides and inorganics in paint. This isn't  
22    highly toxic so the controls are not quite as  
23    stringent. Dust suppression, keeping it wet, maybe  
24    a surfactant, a soap, combination. Beatrice.

25               AUDIENCE MEMBER: I have one more

1 question, or a comment. It seems to me if you're  
2 digging up the trees, you're half-way to digging up  
3 the soil, but let me ask a question. You said at  
4 the beginning we would be hearing more in the next  
5 couple months about -- I wrote down soil vault. I  
6 don't think that's the term you used, on-site soil  
7 repository. Could you give us a sneak preview?

8 MR. SIMPSON: Doug, do you want to talk  
9 about your repository?

10 MR. GREENWELL: And in that  
11 investigation which is similar to what you've heard  
12 tonight at WAG 8 and 9, there's Comprehensive  
13 Remedial Investigation/Feasibility Study that's  
14 been completed. We're preparing to go forth with  
15 the proposed plan the next couple of months. One  
16 of the alternatives that was evaluated at that  
17 site which has large volumes of similar types  
18 of soils as what you've heard here tonight,  
19 cesium-contaminated soil, predominantly, is to look  
20 at developing a consolidation unit not too  
21 dissimilar to the Naval Reactors Facility version  
22 where you take a contaminated area at the Chem  
23 Plant and convert it into an engineered disposal  
24 facility.

25 As part of that study we looked at the

1 fact that there are a large number of these sites  
2 across the INEEL at facilities like Argonne and NRF  
3 that have very similar types of contamination  
4 problems. What we're looking at is, if there is a  
5 way to get some synergy between these sites and  
6 develop one location that could be engineered to  
7 accept a large number of locations of soils of  
8 similar types to see if there's savings that could  
9 be realized by the government. So that alternative  
10 is one of many alternatives being evaluated in that  
11 study, and a proposed plan will be issued for  
12 public comment, I believe late March or April.

13 Right now we're preparing to go through  
14 a national remedy review board process with the  
15 Environmental Protection Agency, and once that  
16 process is complete, then the proposed plan will be  
17 completed and issued. By the way, Keith is also  
18 working on that project, so he gets around.

19 AUDIENCE MEMBER: So it's sized to take  
20 either the Chem Plant soil or sized to take the  
21 Chem Plant soil plus soil from other facilities; is  
22 that what you're saying?

23 MR. GREENWELL: That's correct. Those  
24 are the kinds of alternatives that were evaluated.  
25 We looked at the other INEEL, CERCLA generated

1       soils that could be a result of these other  
2       comprehensive decisions.

3               MR. LEE: Any more questions?

4               MR. SIMPSON: Once again it's the time  
5       of the meeting where you can provide comments for  
6       the record, and once again, state your name and  
7       give your mailing address. Who would like to go  
8       first? Anyone? Okay. I would like to remind you  
9       that the comment period for both of those projects  
10      remains open until February 10th, and each one of  
11      these proposed plans has a comment form in the  
12      back, and you can write your comments down and put  
13      them in the mail to us. I would also like to say  
14      that next month we are going to be doing another  
15      round of meetings to discuss the Waste Area Group 1  
16      which is Test Area North Comprehensive Remedial  
17      Investigation/Feasibility Study, and as Doug  
18      mentioned, we'll be back out on the road in late  
19      March or April to discuss the Chem Plant's  
20      Comprehensive Investigation.

21              And based on what I've seen, I've got  
22      some requests from media for briefings on that and  
23      Doug has been actively involved with the Citizens'  
24      Advisory Board. And based on that, I can say  
25      there's going to be a great deal of interest in the

1 Chem Plant Comprehensive Investigation. So I hope  
2 to see you for those upcoming meetings. Thank  
3 you.

STATE OF IDAHO       )  
                          )   ss.  
County of Ada        )

I, N A N C Y S C H W A R T Z, a Notary  
Public in and for the State of Idaho, do hereby  
certify:

That said hearing was taken down by me  
in shorthand at the time and place therein named  
and thereafter reduced to computer type, and that  
the foregoing transcript contains a true and  
correct record of the said hearing, all done to the  
best of my skill and ability.

I further certify that I have no  
interest in the event of the action.

WITNESS my hand and seal this 23rd day  
of February, 1998.

  
\_\_\_\_\_  
Nancy Schwartz, Notary  
Public in and for the  
State of Idaho

My commission expires:  
September 28, 1998
